

High Power Step-Down Synchronous DC/DC Controller

Features

- Operates from +5V Input
- 0.8V Internal Reference Voltage
 - $\pm 1.5\%$ Accuracy Over Line, Load and Temp.
- 0.8V to V_{CC} Output Range
- Full Duty Cycle Range
 - 0% to 100%
- Internal Loop Compensation
- Internal Soft Start
 - Typical 2ms
- Programmable Over-Current Protection
 - Lossless Sensing Using MOSFET $R_{DS(ON)}$
- Under-Voltage Protection
- Drives External N-Channel MOSFETs
- Shutdown Control
- Small SOP-8 Package

Applications

- Motherboard
- Graphics Cards
- Cable or DSL Modems, Set Top Boxes
- DSP Supplies
- Memory Supplies
- 5V Input DC-DC Regulators
- Distributed Power Supplies

General Description

The APW7057 is a 300kHz constant frequency voltage mode synchronous switching controller that drives external N-channel MOSFETs. When the input supply drops close to output, the upper MOSFET remains on, achieving 100% duty cycle. Internal loop compensation is optimized for fast transient response, eliminating external compensation network. The precision 0.8V reference makes this part suitable for a wide variety of low voltage applications. Soft start is internally set to 2ms, limiting the input in-rush current and preventing the output from overshoot during powering up. The APW7057 has over current and short circuit protections. Over current protection is achieved by monitoring the voltage drop across the high side MOSFET, eliminating the need for a current sensing resistor and short circuit condition is detected through the FB pin. If either fault conditions occur, the APW7057 would initiate the soft start cycle. After three cycles and if the fault condition persists, the controller will be shut down. To restart the controller, either recycle the V_{CC} supply or momentarily pull the OSCSET pin below 1.25V.

The APW7057 can be shutdown by pulling the OCSET pin below 1.25V. In shutdown, both gate drive signals will be low. The controller is available in a small SOP-8 package.

Functional Pin Description

BOOT (Pin 1)

This pin provides the supply voltage to the high side MOSFET driver. A voltage no greater than 13V can be connected to this pin as a supply to the driver. For driving logic level N-channel MOSFET, a bootstrap circuit can be used to create a suitable driver's supply.

UGATE (Pin 2)

This pin provides gate drive for the high-side MOSFET.

GND (Pin 3)

Signal and power ground for the IC. All voltage levels are measured with respect to this pin. Tie this pin to the ground plane through the lowest impedance connection available.

LGATE (Pin 4)

This pin provides the gate drive signal for the low side MOSFET.

VCC (Pin 5)

This is the main bias supply for the controller and its low side MOSFET driver. Must be closely decoupled to GND (Pin 3). **DO NOT** apply a voltage greater than 5.5V to this pin.

FB (Pin 6)

This pin is the inverting input of the error amplifier and it receives the feedback voltage from an exter-

Functional Pin Description

nal resistive divider across the output (V_{OUT}). The output voltage is determined by:

$$V_{OUT} = 0.8V \left(1 + \frac{R_{OUT}}{R_{GND}}\right)$$

where R_{OUT} is the resistor connected between V_{OUT} and FB while R_{GND} is the resistor connected from FB to GND.

OCSET (Pin 7)

This pin serves two functions: as a shutdown control and for setting the over current limit threshold. Pulling this pin below 1.25V shuts the controller down, forcing the UGATE and LGATE signals to be at 0V. A soft start cycle will be initiated upon the release of this pin.

A resistor (R_{OCSET}) connected between this pin and the drain of the high side MOSFET will determine

the over current limit. An internally generated 40uA current source will flow through this resistor, creating a voltage drop. This voltage will be compared with the voltage across the high side MOSFET. The threshold of the over current limit is therefore given by:

$$I_{OI} = \frac{40\mu A \times R_{OCSET}}{R_{DS(ON)}}$$

An over current condition will cycle the soft start function. After three consecutive cycles and if the fault condition persists, the controller will be shut down. To restart the controller, either recycle the V_{CC} supply or momentarily pull the OSCSET pin below 1.25V.

PHASE (Pin 8)

This pin is connected to the source of the high-side MOSFET and is used to monitor the voltage drop across the high-side MOSFET for over-current protection.

Application Information

Component Selection Guidelines

Output Capacitor Selection

The selection of C_{OUT} is determined by the required effective series resistance (ESR) and voltage rating rather than the actual capacitance requirement. Therefore select high performance low ESR capacitors that are intended for switching regulator applications. In some applications, multiple capacitors have to be paralleled to achieve the desired ESR value. If tantalum capacitors are used, make sure they are surge tested by the manufactures. If in doubt, consult the capacitors manufacturer.

Input Capacitor Selection

The input capacitor is chosen based on the voltage rating and the RMS current rating. For reliable operation, select the capacitor voltage rating to be at least 1.3 times higher than the maximum input voltage. The maximum RMS current rating requirement is approximately $I_{OUT}/2$, where I_{OUT} is the load current. During power up, the input capacitors have to handle large amount of surge current. If tantalum capacitors are used, make sure they are surge tested by the manufactures. If in doubt, consult the capacitors manufacturer.

For high frequency decoupling, a ceramic capacitor between 0.1uF to 1uF can be connected between V_{CC} and ground pin.

Inductor Selection

The inductance of the inductor is determined by the output voltage requirement. The larger the inductance, the lower the inductor's current ripple. This will translate into lower output ripple voltage. The ripple current and ripple voltage can be approximated by:

$$I_{RIPPLE} = \frac{V_{IN} - V_{OUT}}{F_s \times L} \times \frac{V_{OUT}}{V_{IN}}$$

$$\Delta V_{OUT} = I_{RIPPLE} \times ESR$$

where F_s is the switching frequency of the regulator.

There is a tradeoff exists between the inductor's ripple current and the regulator load transient response time. A smaller inductor will give the regulator a faster load transient response at the expense of higher ripple current and vice versa. The maximum ripple current occurs at the maximum input voltage. A good starting point is to choose the ripple current to be approximately 30% of the maximum output current.

Once the inductance value has been chosen, select an inductor that is capable of carrying the required peak current without going into saturation. In some type of inductors, especially core that is made of ferrite, the ripple current will increase abruptly when it saturates. This will result in a larger output ripple voltage.

MOSFET Selection

The selection of the N-channel power MOSFETs are determined by the $R_{DS(ON)}$, reverse transfer capacitance (C_{RSS}) and maximum output current requirement. The losses in the MOSFETs have two components: conduction loss and transition loss. For the upper and lower MOSFET, the losses are approximately given by the following :

$$P_{UPPER} = I_{OUT}^2 (1 + TC)(R_{DS(ON)})D + (0.5)(I_{OUT})(V_{IN})(t_{sw})F_s$$

$$P_{LOWER} = I_{OUT}^2 (1 + TC)(R_{DS(ON)})(1-D)$$

where I_{OUT} is the load current

TC is the temperature dependency of $R_{DS(ON)}$

F_s is the switching frequency

t_{sw} is the switching interval

D is the duty cycle

Application Information

Note that both MOSFETs have conduction losses while the upper MOSFET include an additional transition loss. The switching internal, t_{sw} , is a function of the reverse transfer capacitance C_{RSS} . Figure 3 illustrates the switching waveform internal of the MOSFET.

The (1+TC) term is to factor in the temperature dependency of the $R_{DS(ON)}$ and can be extracted from the “ $R_{DS(ON)}$ vs Temperature” curve of the power MOSFET.

Layout Considerations

In high power switching regulator, a correct layout is important to ensure proper operation of the regulator. In general, interconnecting impedances should be minimized by using short, wide printed circuit traces. Signal and power grounds are to be kept separate and finally combined using ground plane construction or

single point grounding. Figure 4 illustrates the layout, with bold lines indicating high current paths. Components along the bold lines should be placed close together. Below is a checklist for your layout:

- Keep the switching nodes (UGATE, LGATE and PHASE) away from sensitive small signal nodes since these nodes are fast moving signals. Therefore keep traces to these nodes as short as possible.
- Decoupling capacitor C_{IN} provides the bulk capacitance and needs to be placed close to the IC since it will provide the MOSFET drivers transient current requirement.
- The ground return of C_{IN} must return to the combine C_{OUT} (-) terminal.
- Capacitor C_{BOOT} should be connected as close to the BOOT and PHASE pins as possible.
