## *SpeedPLUS™* Dual, VARIABLE GAIN AMPLIFIER with Low Noise Preamp

### FEATURES

- **LOW NOISE PREAMP:**
  - Low Input Noise:  $1.25nV/\sqrt{Hz}$
  - Active Termination Noise Reduction
  - Switchable Termination Value
  - 80MHz Bandwidth
  - 5dB to 25dB Gain
  - Differential Input/Output
- **LOW NOISE VARIABLE GAIN AMPLIFIER:**
  - Low Noise VCA:  $3.3nV/\sqrt{Hz}$ , Differential Programming Optimizes Noise Figure
  - 24dB to 45dB Gain
  - 40MHz Bandwidth
  - Differential Input/Output
- **LOW CROSSTALK: 52dB at Max Gain, 5MHz**
- **HIGH-SPEED VARIABLE GAIN ADJUST**
- **SWITCHABLE EXTERNAL PROCESSING**

### APPLICATIONS

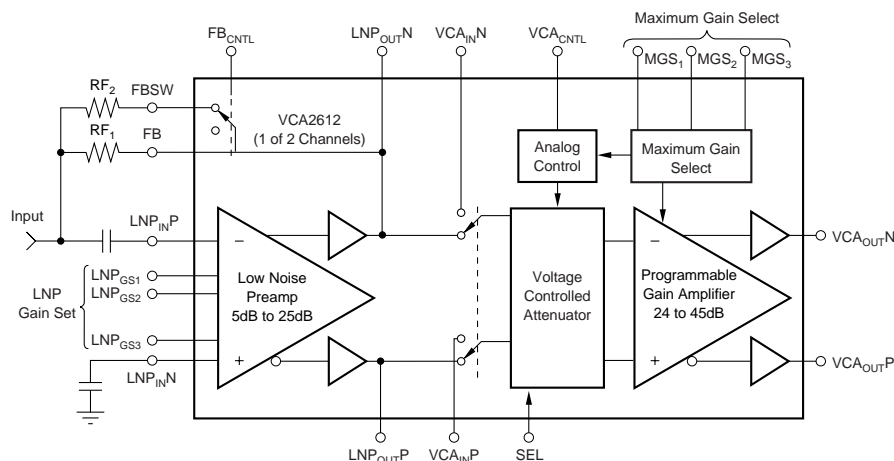

- **ULTRASOUND SYSTEMS**
- **WIRELESS RECEIVERS**
- **TEST EQUIPMENT**

### DESCRIPTION

The VCA2612 is a highly integrated, dual receive channel, signal processing subsystem. Each channel of the product consists of a low noise pre-amplifier (LNP) and a Variable Gain Amplifier (VGA). The LNP circuit provides the necessary connections to implement Active Termination (AT), a method of cable termination which results in up to 4.6dB noise figure improvement. Different cable termination characteristics can be accommodated by utilizing the VCA2612's switchable LNA feedback pins. The LNP has the ability to accept both differential and single ended inputs, and generates a differential output signal. The LNP provides strappable gains of 5dB, 17dB, 22dB and 25dB.

The output of the LNP can be accessed externally for further signal processing, or fed directly into the VGA. The VCA2612's VGA section consists of two parts, the Voltage Controlled Attenuator (VCA) and the Programmable Gain Amplifier (PGA). The gain and gain range of the Programmable Gain Amplifier can be digitally programmed. The combination of these two programmable elements results in a variable gain ranging from 0dB up to a maximum gain as defined by the user through external connections. The output of the VGA can be used in either a single-ended or differential mode to drive high performance analog-to-digital converters.

The VCA2612 also features low crosstalk and outstanding distortion performance. The combination of low noise, and gain range programmability make the VCA2612 a versatile building block in a number of applications where noise performance is critical. The VCA2612 is available in a TQFP-48 package.

## ELECTROSTATIC DISCHARGE SENSITIVITY

This integrated circuit can be damaged by ESD. Burr-Brown recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

## ABSOLUTE MAXIMUM RATINGS

Power Supply (+V <sub>S</sub> ) .....	+6V
Analog Input .....	-0.3V to (+V <sub>S</sub> + 0.3V)
Logic Input .....	-0.3V to (+V <sub>S</sub> + 0.3V)
Case Temperature .....	+100°C
Junction Temperature .....	+150°C
Storage Temperature .....	-40°C to +150°C

## PACKAGE/ORDERING INFORMATION

PRODUCT	PACKAGE	PACKAGE DRAWING NUMBER	SPECIFIED TEMPERATURE RANGE	PACKAGE MARKING	ORDERING NUMBER <sup>(1)</sup>	TRANSPORT MEDIA
VCA2612Y "	TQFP-48 Surface Mount "	355 "	-40°C to +85°C "	A12 "	VCA2612Y/250 VCA2612Y/2K	Tape and Reel "

NOTE: (1) Models with a slash (/) are available only in Tape and Reel in the quantities indicated (e.g., /2K indicates 2000 devices per reel). Ordering 2000 pieces of "VCA2612Y/2K" will get a single 2000-piece Tape and Reel.

# THEORY OF OPERATION

The VCA2612 is a dual-channel system consisting of three primary blocks: a Low Noise Preamp (LNP), a Voltage Controlled Attenuator (VCA) and a Programmable Gain Amplifier (PGA). For greater system flexibility, an onboard multiplexer provides for the VCA inputs, selecting either the LNP outputs or external signal inputs. Figure 1 shows a simplified block diagram of the dual channel system.

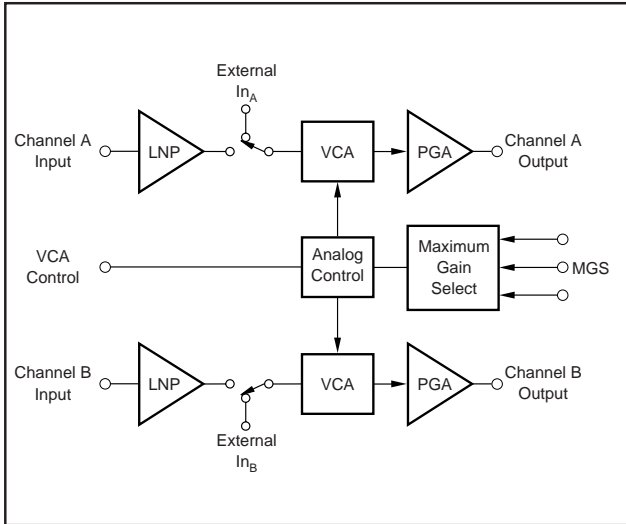

FIGURE 1. Simplified Block Diagram of the VCA2612.

## LNP—OVERVIEW

The LNP input may be connected to provide active-feedback signal termination, achieving lower system noise performance than conventional passive shunt termination. Even lower noise performance is obtained if signal termination is not required. The unterminated LNP input impedance is 600kΩ. The LNP can process fully differential or single-ended signals in each channel. Differential signal processing results in significantly reduced 2nd-harmonic distortion and improved rejection of common-mode and power supply noise. The first gain stage of the LNP is AC coupled into its output buffer with a 44μs time constant (3.6kHz high-pass characteristic). The buffered LNP outputs are designed to drive the succeeding VCA directly or, if desired, external loads as low as 135Ω with minimal impact on signal distortion. The LNP employs very low impedance local feedback to achieve stable gain with the lowest possible noise and distortion. Four pin-programmable gain settings are available: 5dB, 17dB, 22dB and 25dB. Additional intermediate gains can be programmed by adding trim resistors between the Gain Strap programming pins.

The common-mode DC level at the LNP output is nominally 2.5V, matching the input common-mode requirement of the VCA for simple direct coupling. When external signals are fed to the VCA, they should also be set up with a 2.5VDC common-mode level. Figure 2 shows a circuit that demonstrates the recommended coupling method using an external

op amp. The “V<sub>CM</sub>” node shown in the drawing is the V<sub>CM</sub> output (pin 19). Typical R and C values are shown, yielding a high-pass time constant similar to that of the LNP. If a different common-mode referencing method is used, it is important that the common-mode level be within 10mV of the V<sub>CM</sub> output for proper operation.

FIGURE 2. Recommended Signal Coupling.

## VCA—OVERVIEW

The magnitude of the differential VCA input signal (from the LNP or an external source) is reduced by a programmable attenuation factor, set by the analog VCA Control Voltage (VCA<sub>CNTL</sub>) at pin 43. The maximum attenuation factor is further programmable by using the three MGS bits (pins 40-42). Figure 3 illustrates this dual-adjustable characteristic. Internally, the signal is attenuated by having the analog VCA<sub>CNTL</sub> vary the channel resistance of a set of shunt-connected FET transistors. The MGS bits effectively adjust the overall size of the shunt FET by switching parallel components in or out under logic control. At any given maximum gain setting, the analog variable gain characteristic is linear in dB as a function of the control voltage, and is created as a piecewise approximation of an ideal dB-linear transfer function. The VCA gain control circuitry is common to both channels of the VCA2612.

FIGURE 3. Swept Attenuator Characteristic.

## PGA OVERVIEW AND OVERALL DEVICE CHARACTERISTICS

The differential output of the VCA attenuator is then amplified by the PGA circuit block. This post-amplifier is programmed by the same MGS bits that control the VCA attenuator, yielding an overall swept-gain amplifier characteristic in which the VCA • PGA gain varies from 0dB (unity) to a programmable peak gain of (24, 27, 30, 33, 36, 39, 42, 45) dB.

The “GAIN vs VCA<sub>CNTL</sub>” curve on page 5 shows the composite gain control characteristic of the entire VCA2612. Setting VCA<sub>CNTL</sub> to 3.0V causes the digital MGS gain control to step in 3dB increments. Setting VCA<sub>CNTL</sub> to 0V causes all the MGS-controlled gain curves to converge at one point. The gain at the convergence point is the LNP gain less 6dB, because the measurement setup looks at only one side of the differential PGA output, resulting in 6dB lower signal amplitude.

## ADDITIONAL FEATURES—OVERVIEW

Overload protection stages are placed between the attenuator and the PGA, providing a symmetrically clipped output whenever the input becomes large enough to overload the PGA. A comparator senses the overload signal amplitude and substitutes a fixed DC level to prevent undesirable overload recovery effects. As with the previous stages, the VCA is AC coupled into the PGA. In this case, the coupling time constant varies from 5μs at the highest gain (46dB) to 59μs at the lowest gain (25dB).

The VCA2612 includes a built-in reference, common to both channels, to supply a regulated voltage for critical areas of the circuit. This reduces the susceptibility to power supply variation, ripple and noise. In addition, separate power supply and ground connections are provided for each channel and for the reference circuitry, further reducing interchannel cross-talk.

Further details regarding the design, operation and use of each circuit block are provided in the following sections.

## LOW NOISE PREAMPLIFIER (LNP)—DETAIL

The LNP is designed to achieve a low noise figure, especially when employing active termination. Figure 4 is a simplified schematic of the LNP, illustrating the differential input and output capability. The input stage employs low resistance local feedback to achieve stable low noise, low distortion performance with very high input impedance. Normally, low noise circuits exhibit high power consumption due to the large bias currents required in both input and output stages. The LNP uses a patented technique that combines the input and output stages such that they share the same bias current. Transistors Q4 and Q5 amplify the signal at the gate-source input of Q4, the +IN side of the LNP. The signal is further amplified by the Q1 and Q2 stage, and then by the final Q3 and R<sub>L</sub> gain stage, which uses the same bias current as the input devices Q4 and Q5. Devices Q6 through Q10 play the same role for signals on the -IN side.

The differential gain of the LNP is given in Equation (1):

$$\text{Gain} = 2 \cdot \left[ \frac{R_L}{R_S} \right] \quad (1)$$

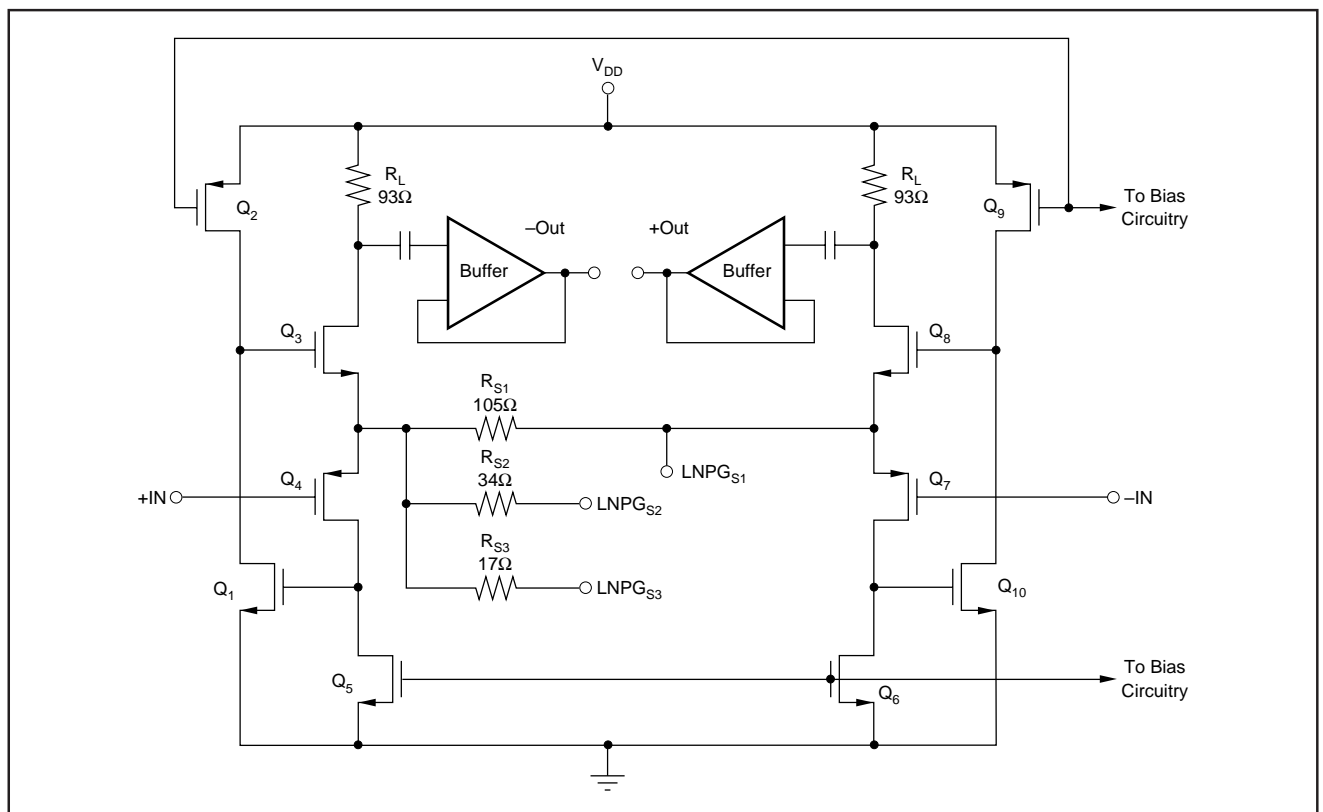

FIGURE 4. Schematic of the Low Noise Pre-Amplifier (LNP).

where  $R_L$  is the load resistor in the drains of Q3 and Q8, and  $R_S$  is the resistor connected between the sources of the input transistors Q4 and Q7. The connections for various  $R_S$  combinations are brought out to device pins  $LNPG_{S1}$ ,  $LNPG_{S2}$  and  $LNPG_{S3}$  (pins 13-15 for channel A, 22-24 for channel B). These Gain Strap pins allow the user to establish one of four fixed LNP gain options as shown in Table I.

LNP PIN STRAPPING	LNP GAIN (dB)
$LNPG_{S1}$ , $LNPG_{S2}$ , $LNPG_{S3}$ Connected Together	25
$LNPG_{S1}$ Connected to $LNPG_{S3}$	22
$LNPG_{S1}$ Connected to $LNPG_{S2}$	17
All Pins Open	5

TABLE I. Pin Strappings of the LNP for Various Gains.

It is also possible to create other gain settings by connecting an external resistor between  $LNPG_{S1}$  on one side, and  $LNPG_{S2}$  and/or  $LNPG_{S3}$  on the other. In that case, the internal resistor values shown in Figure 4 should be combined with the external resistor to calculate the effective value of  $R_S$  for use in Equation (1). The resulting expression for external resistor value is given in Equation (2).

$$R_{EXT} = \frac{2R_{S1}R_L + 2R_{FIX}R_L - Gain \cdot R_{S1}R_{FIX}}{Gain \cdot R_{S1} - 2R_L} \quad (2)$$

where  $R_{EXT}$  is the externally selected resistor value needed to achieve the desired gain setting,  $R_{S1}$  is the fixed parallel resistor in Figure 4, and  $R_{FIX}$  is the effective fixed value of the remaining internal resistors:  $R_{S2}$ ,  $R_{S3}$  or  $(R_{S2} \parallel R_{S3})$  depending on the pin connections.

Note that the best process and temperature stability will be achieved by using the pre-programmed fixed gain options of Table I, since the gain is then set entirely by internal resistor ratios, which are typically accurate to  $\pm 0.5\%$ , and track quite well over process and temperature. When combining external resistors with the internal values to create an effective  $R_S$  value, note that the internal resistors have a typical temperature coefficient of  $+700\text{ppm}/^\circ\text{C}$  and an absolute value tolerance of approximately  $\pm 5\%$ , yielding somewhat less predictable and stable gain settings. With or without external resistors, the board layout should use short Gain Strap connections to minimize parasitic resistance and inductance effects.

The overall noise performance of the VCA2612 will vary as a function of gain. Table II shows the typical input-and output-referred noise densities of the entire VCA2612 for maximum VCA and PGA gain; i.e.,  $VCA_{CNTL}$  set to 3.0V and all MGS bits set to "1". Note that the input-referred noise values include the contribution of a  $50\Omega$  fixed source impedance, and are therefore somewhat larger than the intrinsic input noise. As the LNP gain is reduced, the noise contribution from the VCA/PGA portion becomes more significant, resulting in higher input-referred noise. However, the output-referred noise, which is indicative of the overall SNR at that gain setting, is reduced.

To preserve the low noise performance of the LNP, the user should take care to minimize resistance in the input lead. A parasitic resistance of only  $10\Omega$  will contribute  $0.4nV/\sqrt{\text{Hz}}$ .

LNP GAIN (dB)	NOISE (nv/ $\sqrt{\text{Hz}}$ )	
	Input-Referred	Output-Referred
25	1.54	2260
22	1.59	1650
17	1.82	1060
5	4.07	597

TABLE II. Noise Performance for  $MGS = 111$  and  $VCA_{CNTL} = 3.0V$ .

The LNP is capable of generating a 2Vp-p differential signal. The maximum signal at the LNP input is therefore 2Vp-p divided by the LNP gain. An input signal greater than this would exceed the linear range of the LNP, an especially important consideration at low LNP gain settings.

### ACTIVE FEEDBACK WITH THE LNP

One of the key features of the LNP architecture is the ability to employ active-feedback termination to achieve superior noise performance. Active feedback termination achieves a lower noise figure than conventional shunt termination, essentially because no signal current is wasted in the termination resistor itself. Another way to understand this is as follows: Consider first that the input source, at the far end of the signal cable has a cable-matching source resistance of  $R_S$ . Using conventional shunt termination at the LNP input, a second terminating resistor of value  $R_S$  is connected to ground. Therefore, the signal loss is 6dB due to the voltage divider action of the series and shunt  $R_S$  resistors. The effective source resistance has been reduced by the same factor of 2, but the noise contribution has been reduced by only the  $\sqrt{2}$ , only a 3dB reduction. Therefore, the net theoretical SNR degradation is 3dB, assuming a noise-free amplifier input. (In practice, the amplifier noise contribution will degrade both the unterminated and the terminated noise figures, somewhat reducing the distinction between them.)

Figure 5 shows an amplifier using active feedback. This diagram appears very similar to a traditional inverting amplifier. However, the analysis is somewhat different because the gain "A" in this case is not a very large open-loop op amp gain; rather it is the relatively low and controlled gain of the LNP itself. Thus, the impedance at the inverting amplifier terminal will be reduced by a finite amount, as given in the familiar relationship of Equation (3):

$$R_{IN} = \frac{R_F}{(1 + A)} \quad (3)$$

where  $R_F$  is the feedback resistor (supplied externally between the  $LNP_{INP}$  and FB terminals for each channel), A is the user-selected gain of the LNP, and  $R_{IN}$  is the resulting amplifier input impedance with active feedback. In this case, unlike the conventional termination above, both the signal voltage and the  $R_S$  noise are attenuated by the same factor of

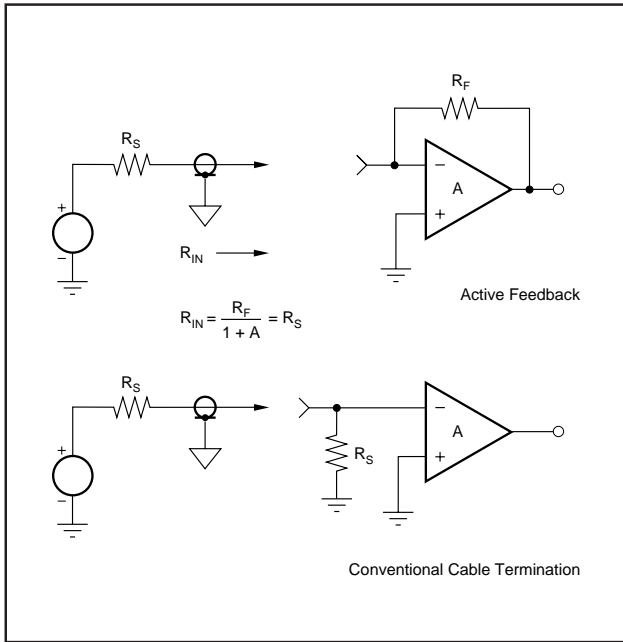

FIGURE 5. Configurations for Active Feedback and Conventional Cable Termination.

two (6dB) before being re-amplified by the “A” gain setting. This avoids the extra 3dB degradation due to the square-root effect described above, the key advantage of the active termination technique.

As mentioned above, the previous explanation ignored the input noise contribution of the LNP itself. Also, the noise contribution of the feedback resistor must be included for a completely correct analysis. The curves given in Figures 6 and 7 allow the VCA2612 user to compare the achievable noise figure for active and conventional termination methods. The left-most set of data points in each graph give the results for typical 50Ω cable termination, showing the worst noise figure but also the greatest advantage of the active feedback method.

FIGURE 6. Noise Figure for Active Termination.

FIGURE 7. Noise Figure for Conventional Termination.

A switch, controlled by the  $FBSW_{CNTL}$  signal on pin 45, enables the user to reduce the feedback resistance by adding an additional parallel component, connected between the  $LNP_{INP}$  and  $SWFB$  terminals. The two different values of feedback resistance will result in two different values of active-feedback input impedance. Thus, the active-feedback impedance can be optimized at two different LNP gain settings. The switch is connected at the buffered output of the LNP and has an “ON” resistance of approximately 1Ω.

When employing active feedback, the user should be careful to avoid low-frequency instability or overload problems. Figure 8 illustrates the various low-frequency time constants. Referring again to the input resistance calculation of Equation (3), and considering that the gain term “A” falls off below 3.6kHz, it is evident that the effective LNP input impedance will rise below 3.6kHz, with a DC limit of approximately  $R_F$ . To avoid interaction with the feedback pole/zero at low frequencies, and to avoid the higher signal levels resulting from the rising impedance characteristic, it is recommended that the external  $R_F C_C$  time constant be set to about 5μs.

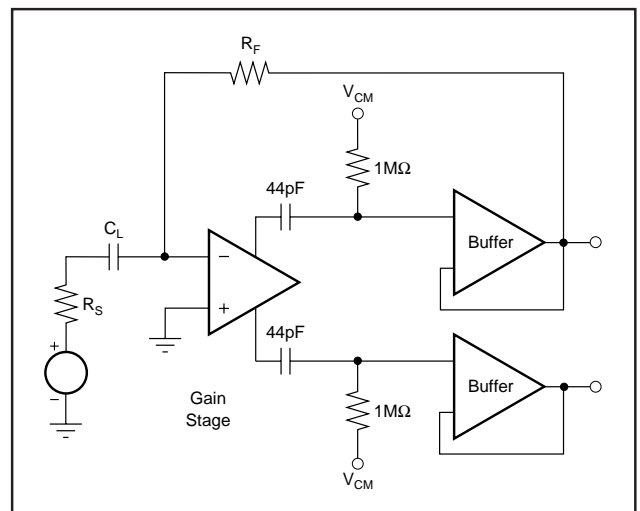

FIGURE 8. Low Frequency LNP Time Constants.

Achieving the best active feedback architecture is difficult with conventional op amp circuit structures. The overall gain “A” must be negative in order to close the feedback loop, the input impedance must be high to maintain low current noise and good gain accuracy, but the gain ratio must be set with very low value resistors to maintain good voltage noise. Using a two-amplifier configuration (non-inverting for high impedance plus inverting for negative feedback reasons) results in excessive phase lag and stability problems when the loop is closed. The VCA2612 uses a patented architecture that achieves these requirements, with the additional benefits of low power dissipation and differential signal handling at both input and output.

For greatest flexibility and lowest noise, the user may wish to shape the frequency response of the LNP. The COMP1 and COMP2 pins for each channel (pins 10 and 11 for channel A, pins 26 and 27 for channel B) correspond to the drains of Q3 and Q8 in Figure 4. A capacitor placed between these pins will create a single-pole low pass response, in which the effective “R” of the “RC” time constant is approximately 186Ω.

### LNP OUTPUT BUFFER

The differential LNP output is buffered by wideband class AB voltage followers which are designed to drive low impedance loads. This is necessary to maintain LNP gain accuracy, since the VCA input exhibits gain-dependent input impedance. The buffers are also useful when the LNP output is brought out to drive external filters or other signal processing circuitry. Good distortion performance is maintained with buffer loads as low as 135Ω. As mentioned previously, the buffer inputs are AC coupled to the LNP outputs with a 3.6kHz high-pass characteristic, and the DC common mode level is maintained at the correct  $V_{CM}$  for compatibility with the VCA input.

### VOLTAGE-CONTROLLED ATTENUATOR (VCA)—DETAIL

The VCA is designed to have a “dB-linear” attenuation characteristic, i.e. the gain loss in dB is constant for each

equal increment of the  $VCA_{CNTL}$  control voltage. Figure 9 shows a block diagram of the VCA. The attenuator is essentially a variable voltage divider consisting of one series input resistor,  $R_S$ , and ten identical shunt FETs, placed in parallel and controlled by sequentially activated clipping amplifiers. Each clipping amplifier can be thought of as a specialized voltage comparator with a “soft” transfer characteristic and well-controlled output limit voltages. The reference voltages V1 through V10 are equally spaced over the 0V to 3.0V control voltage range. As the control voltage rises through the input range of each clipping amplifier, the amplifier output will rise from 0V (FET completely “ON”) to  $V_{CM} - V_T$  (FET nearly “OFF”), where  $V_{CM}$  is the common source voltage and  $V_T$  is the threshold voltage of the FET. As each FET approaches its “OFF” state and the control voltage continues to rise, the next clipping amplifier/FET combination takes over for the next portion of the piecewise-linear attenuation characteristic. Thus, low control voltages have most of the FETs turned “ON”, while high control voltages have most turned “OFF”. Each FET acts to decrease the shunt resistance of the voltage divider formed by  $R_S$  and the parallel FET network.

The attenuator is comprised of two sections, with five parallel clipping amplifier/FET combinations in each. Special reference circuitry is provided so that the  $(V_{CM} - V_T)$  limit voltage will track temperature and IC process variations, minimizing the effects on the attenuator control characteristic.

In addition to the analog  $VCA_{CNTL}$  gain setting input, the attenuator architecture provides digitally programmable adjustment in eight steps, via the three Maximum Gain Setting (MGS) bits. These adjust the maximum achievable gain (corresponding to minimum attenuation in the VCA, with  $VCA_{CNTL} = 3.0V$ ) in 3dB increments. This function is accomplished by providing multiple FET sub-elements for each of the Q1 to Q10 FET shunt elements shown in Figure 9. In the simplified diagram of Figure 10, each shunt FET is shown as two sub-elements,  $Q_{NA}$  and  $Q_{NB}$ . Selector switches, driven by the MGS bits, activate either or both of the sub-element FETs to adjust the maximum  $R_{ON}$  and thus achieve the stepped attenuation options.

FIGURE 9. Piecewise Approximation to Logarithmic Control Characteristics.

The VCA can be used to process either differential or single-ended signals. Fully differential operation will reduce 2nd-harmonic distortion by about 10dB for full-scale signals.

Input impedance of the VCA will vary with gain setting, due to the changing resistances of the programmable voltage divider structure. At large attenuation factors (i.e., low gain settings), the impedance will approach the series resistor value of approximately 135Ω.

As with the LNP stage, the VCA output is AC coupled into the PGA. This means that the attenuation-dependent DC common-mode voltage will not propagate into the PGA, and so the PGA's DC output level will remain constant.

Finally, note that the VCA<sub>CNTL</sub> input consists of FET gate inputs. This provides very high impedance and ensures that multiple VCA2612 devices may be connected in parallel with no significant loading effects.

### OVERLOAD RECOVERY CIRCUITRY—DETAIL

With a maximum overall gain of 70dB, the VCA2612 is prone to signal overloading. Such a condition may occur in either the LNP or the PGA depending on the various gain and attenuation settings available. The LNP is designed to

produce low-distortion outputs as large as 1Vp-p single-ended (2Vp-p differential). Therefore the maximum input signal for linear operation is 2Vp-p divided by the LNP differential gain setting. Clamping circuits in the LNP ensure that larger input amplitudes will exhibit symmetrical clipping and short recovery times. The VCA itself, being basically a voltage divider, is intrinsically free of overload conditions. However, the PGA post-amplifier is vulnerable to sudden overload, particularly at high gain settings. Rapid overload recovery is essential in many signal processing applications such as ultrasound imaging. A special comparator circuit is provided at the PGA input which detects overrange signals (detection level dependent on PGA gain setting). When the signal exceeds the comparator input threshold, the VCA output is blocked and an appropriate fixed DC level is substituted, providing fast and clean overload recovery. The basic architecture is shown in Figure 11. Both high and low overrange conditions are sensed and corrected by this circuit.

Figures 12 and 13 show typical overload recovery waveforms with MGS = 100, for VCA • PGA minimum gain (0dB) and maximum gain (36dB), respectively. LNP gain is set to 25dB in both cases.

### PGA POST-AMPLIFIER—DETAIL

Figure 14 shows a simplified circuit diagram of the PGA block. As described previously, the PGA gain is programmed with the same MGS bits which control the VCA maximum attenuation factor. Specifically, the PGA gain at each MGS setting is the inverse (reciprocal) of the maximum VCA attenuation at that setting. Therefore, the VCA • PGA overall gain will always be 0dB (unity) when the analog VCA<sub>CNTL</sub> input is set to 0V (= maximum attenuation). For VCA<sub>CNTL</sub> = 3V (no attenuation), the VCA • PGA gain will be controlled by the programmed PGA gain (24 to 45 dB in 3dB steps).

For clarity, the gain and attenuation factors are detailed in Table III.

MGS SETTING	VCA GAIN min to max VCA <sub>CNTL</sub> = 0V to 3V	DIFFERENTIAL PGA GAIN	VCA • PGA GAIN min to max
000	-24dB to 0dB	24dB	0dB to 24dB
001	-27dB to 0dB	27dB	0dB to 27dB
010	-30dB to 0dB	30dB	0dB to 30dB
011	-33dB to 0dB	33dB	0dB to 33dB
100	-36dB to 0dB	36dB	0dB to 36dB
101	-39dB to 0dB	39dB	0dB to 39dB
110	-42dB to 0dB	42dB	0dB to 42dB
101	-45dB to 0dB	45dB	0dB to 45dB

TABLE III. MGS Settings.

The PGA architecture consists of a differential, programmable-gain voltage to current converter stage followed by transimpedance amplifiers to create and buffer each side of the differential output. The circuitry associated with the voltage to current converter is similar to that previously described for the LNP, with the addition of eight selectable PGA gain-setting resistor combinations (controlled by the MGS bits) in place of the fixed resistor network used in the LNP. Low input noise is also a requirement of the PGA design due to the large amount of signal attenuation which can be inserted between the LNP and the PGA. At minimum VCA attenuation (used for small input signals) the LNP noise dominates; at maximum VCA attenuation (large input signals) the PGA noise dominates. Note that if the PGA output is used single-ended, the apparent gain will be 6dB lower.
