### DESCRIPTION:

The LS7210 is a monolithic MOS integrated circuit programmable digital timer that can generate a delay in the range of 6ms to infinity. The delay is programmed by 5 binary weighted input bits in combination with the time base provided. The chip can be operated in four different modes: Delayed Operate, Delayed Release, Dual Delay and One Shot. These modes are selected by the control inputs A and B.

### INPUT/OUTPUT DESCRIPTION:

#### OSCILLATOR Input (Pin 5)

The frequency of the internal oscillator is set by an RC network connected to the OSC input, as shown in Figure 2. The nominal oscillator frequency,  $f$ , at room temperature is given by  $f = 1/RC$  where R values range from a minimum of 47K to a maximum 3M.

**NOTE:** Oscillation accuracy from chip to chip for a fixed value of RC, is  $\pm 10\%$ . (Parts can supplied to tighter tolerances.)

#### EXTERNAL CLOCK Input (Pin 6)

If the internal oscillator is not used, the chip can be driven by an external clock applied to this input.

#### CLOCK SELECT Input (Pin 4)

The internal oscillator or the external clock is selected by the proper logic level applied to this input. A logic 1 selects the external clock and logic 0 selects the internal oscillator. (See Note 1)

#### TRIGGER Input (Pin 3)

A positive or a negative transition at the trigger input initiates a delay in turning on or off the output. A negative transition always turns on the output with or without delay depending on the selected mode. A positive transition at the trigger input always turns off the output (with the exception of one-shot mode) with or without delay depending on the selected mode. The delay is a function of the time base frequency and the weighting factor programmed at the weighting bit inputs. The trigger input is clocked into the input latch with the negative edge of the selected time base clock. All timings begin after the latch has been set up. (See Note 1)

#### WEIGHTING FACTOR Inputs, $\overline{WB0}$ - $\overline{WB4}$ (Pins 12-8)

A delay from the trigger input to the output is programmed by applying 1's complement binary weighted numbers at these 5 inputs. (See Note 1) The exact equation for the delay is:

$$\text{Delay} = \frac{(1 + 1, 023N)}{f} \quad \begin{matrix} f = \text{Oscillation Frequency} \\ N = \text{Weighting Factor} \end{matrix}$$

TABLE 1. WEIGHTING BITS ASSIGNMENTS

INPUTS	VALUE
$\overline{WB0}$	1
$\overline{WB1}$	2
$\overline{WB2}$	4
$\overline{WB3}$	8
$\overline{WB4}$	16

**Example:** For a weighting factor of 25, inputs  $\overline{WB4}$ ,  $\overline{WB3}$ , and  $\overline{WB0}$  should be programmed to logic 0.

#### MODE SELECT Inputs A, B (Pins 2, 1)

The chip can be programmed to operate in four different modes by applying the logic levels to inputs A and B as indicated in Table 2. The mode select inputs are clocked into the input latches with the negative edge of the time base clock. These inputs should not be changed while a delay timing is in progress. (See Note 1)

TABLE 2. MODE SELECTION

CONTROL		MODE
A	B	
1	1	Dual Delay
1	0	Delayed Release
0	1	Delayed Operate
0	0	One Shot

#### $\overline{OUT}$ Output (Pin 13)

The output is an open drain FET. To obtain proper switching of the output between Logic 0 and 1 levels, an external pull down resistor to V<sub>DD</sub> must be used. If the output is used only as a current source, no such pull down is needed. The output is logically inverted with respect to the trigger input.

#### V<sub>SS</sub>, V<sub>DD</sub> (Pins 14, 9)

Supply voltage positive, negative terminals.

**NOTE 1:** These inputs have internal pullup resistors.

**MODE DEFINITION TIMING DIAGRAM:** (See Figure 3)**DUAL DELAY MODE**

This is the Default Mode when the inputs A and B are left unprogrammed. The function of the Dual Delay mode is to provide a time delay on both the turn-on and turn-off of the output. Once turned on, the output will remain on as long as the trigger input is Logic 0. Once turned off, the output will remain off as long as the trigger input is a logic 1.

**DELAYED OPERATE MODE**

This mode causes a retriggerable delay in turning the output on in response to a negative edge at the trigger input. The output is turned off without delay in response to a positive transition at the trigger input.

**DELAYED RELEASE MODE**

This mode causes a retriggerable delay in turning off the output whenever there is a positive transition at the trigger input. The output is turned on without delay in response to a negative transition at the trigger input.

**ONE-SHOT MODE**

In this mode, the chip functions like a retriggerable monostable multi-vibrator. The output is turned on whenever there is a negative transition at the trigger input. At the end of the programmed delay, the output is turned off automatically. If there is a negative transition at the trigger input before the delay is over, the delay is restarted. A positive transition at the trigger input has no effect on the output in this mode. **NOTE:** In One-Shot mode, the TRIGGER input must be held at logic 1 during a power-up.
