
#### Abstract

General Description The MAX1300/MAX1301 multirange, low-power, 16-bit, successive-approximation, analog-to-digital converters (ADCs) operate from a single +5 V supply and achieve throughput rates up to 115 ksps . A separate digital supply allows digital interfacing with 2.7 V to 5.25 V systems using the SPI ${ }^{\text {TM }}$-/QSPITM_/MICROWIRE ${ }^{\text {TM }}$-compatible serial interface. Partial power-down mode reduces the supply current to 1.3 mA (typ). Full power-down mode reduces the power-supply current to $1 \mu \mathrm{~A}$ (typ). The MAX1300 provides eight (single-ended) or four (true differential) analog input channels. The MAX1301 provides four (single-ended) or two (true differential) analog input channels. Each analog input channel is independently software programmable for seven sin-gle-ended input ranges ( 0 to +6 V , -6 V to 0,0 to +12 V , -12 V to $0, \pm 3 \mathrm{~V}, \pm 6 \mathrm{~V}$, and $\pm 12 \mathrm{~V}$ ), and three differential input ranges $( \pm 6 \mathrm{~V}, \pm 12 \mathrm{~V}, \pm 24 \mathrm{~V})$. An on-chip +4.096 V reference offers a small convenient ADC solution. The MAX1300/MAX1301 also accept an external reference voltage between 3.800 V and 4.136 V . The MAX1300 is available in a 24 -pin TSSOP package and the MAX1301 is available in a 20-pin TSSOP package. Each device is specified for operation from $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$.

Applications
Industrial Control Systems
Data-Acquisition Systems
Avionics
Robotics

- Software-Programmable Input Range for Each Channel
- Single-Ended Input Ranges

0 to $+6 \mathrm{~V},-6 \mathrm{~V}$ to 0,0 to $+12 \mathrm{~V},-12 \mathrm{~V}$ to $0, \pm 3 \mathrm{~V}$, $\pm 6 \mathrm{~V}$, and $\pm 12 \mathrm{~V}$

- Differential Input Ranges
$\pm 6 \mathrm{~V}, \pm 12 \mathrm{~V}$, and $\pm 24 \mathrm{~V}$
- Eight Single-Ended or Four Differential Analog Inputs (MAX1300)
- Four Single-Ended or Two Differential Analog Inputs (MAX1301)
- $\pm 16.5 \mathrm{~V}$ Overvoltage Tolerant Inputs
- Internal or External Reference
- 115ksps Maximum Sample Rate
- Single +5V Power Supply
- 20-/24-Pin TSSOP Package

Ordering Information

## 8-/4-Channel, $\pm 12 \mathrm{~V}$ Multirange Inputs, Serial 16-Bit ADCs

## ABSOLUTE MAXIMUM RATINGS

| AVDD1 to AGND1 | -0.3V to +6V |
| :---: | :---: |
| AVDD2 to AGND2 . | -0.3V to +6V |
| DVDD to DGND | -0.3V to +6V |
| DVDDO to DGNDO | -0.3V to +6V |
| DVDD to DVDDO | -0.3 V to +6V |
| DVDD, DVDDO to | -0.3V to +6V |
| AVDD1, DVDD, DV | -0.3V to +6V |
| DGND, DGNDO, AG | -0.3V to +0.3V |
| $\overline{\mathrm{CS}}$, SCLK, DIN, DO |  |
| DGNDO.. | VDDO + 0.3V) |

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Note 1: Parameter tested at $A V_{D D 1}=A V_{D D 2}=D V_{D D}=D V_{D D O}=5 \mathrm{~V}$.
Note 2: See definitions in the Parameter Definitions section at the end of the data sheet.
Note 3: Guaranteed by correlation with single-ended measurements.
Note 4: Not production tested. Guaranteed by design.
Note 5: To ensure external reference operation, VREFCAP must exceed (AVDD1-0.1V). To ensure internal reference operation, VREFCAP must be below (AVDD1-0.4V). Bypassing REFCAP with a $0.1 \mu \mathrm{~F}$ or larger capacitor to AGND1 sets $\mathrm{V}_{\mathrm{REFCF}} \mathrm{CAP} \approx 4.096 \mathrm{~V}$. The transition point between internal reference mode and external reference mode lies between the REFCAP buffer disable threshold minimum and maximum values (Figures 17 and 18)
Note 6: The SCLK duty cycle can vary between $40 \%$ and $60 \%$, as long as the tCL and tch timing requirements are met.

## Typical Operating Characteristics

$\left(A V_{D D 1}=A V_{D D 2}=D V_{D D}=D V_{D D O}=5 V, A G N D 1=D G N D=D G N D O=A G N D 2=A G N D 3=0, f C L K=3.5 M H z(50 \%\right.$ duty cycle), external clock mode, $\mathrm{V}_{\mathrm{REF}}=4.096 \mathrm{~V}$ (external reference operation), REFCAP $=A V_{D D 1}$, maximum single-ended bipolar input range, CDOUT $=50 \mathrm{pF}, \mathrm{CSSTRB}=50 \mathrm{pF}$; unless otherwise noted. )

## 8-/4-Channel, $\pm 12 \mathrm{~V}$ Multirange Inputs, Serial 16-Bit ADCs

Typical Operating Characteristics (continued)
$\left(A V_{D D 1}=A V_{D D 2}=D V_{D D}=D V_{D D O}=5 V, A G N D 1=D G N D=D G N D O=A G N D 2=A G N D 3=0, f C L K=3.5 M H z(50 \%\right.$ duty cycle), external clock mode, $\mathrm{V}_{\text {REF }}=4.096 \mathrm{~V}$ (external reference operation), REFCAP $=A V_{\text {DD1 }}$, maximum single-ended bipolar input range, $C_{\text {DOUT }}=50 \mathrm{pF}, \mathrm{C}$ SSTRB $=50 \mathrm{pF}$; unless otherwise noted. )

## 8-/4-Channel, $\pm 12 \mathrm{~V}$ Multirange Inputs, Serial 16-Bit ADCs

## Typical Operating Characteristics (continued)

$\left(A V_{D D 1}=A V_{D D 2}=D V_{D D}=D V_{D D O}=5 V, A G N D 1=D G N D=D G N D O=A G N D 2=A G N D 3=0, f C L K=3.5 M H z(50 \%\right.$ duty cycle), external clock mode, $\mathrm{V}_{\text {REF }}=4.096 \mathrm{~V}$ (external reference operation), REFCAP $=A V_{D D 1}$, maximum single-ended bipolar input range, CDOUT $=50 \mathrm{pF}, \mathrm{CSSTRB}=50 \mathrm{pF}$; unless otherwise noted.

Note 7: For partial power-down and full power-down modes, external clock mode was used for a burst of continuous samples. Partial power-down or full power-down modes were entered thereafter. By using this method, the conversion rate was found by averaging the number of conversions over the time starting from the first conversion to the end of the partial power-down or full power-down modes.

| 5 | 6 | CH3 | Analog Input Channel 3 |
| 6 | - | CH4 | Analog Input Channel 4 |
| 7 | - | CH5 | Analog Input Channel 5 |
| 8 | - | CH6 | Analog Input Channel 6 |
| 9 | - | CH7 | Analog Input Channel 7 |
| 10 | 7 | $\overline{\mathrm{CS}}$ | Active-Low Chip-Select Input. When $\overline{\mathrm{CS}}$ is low, data is clocked into the device from DIN on the rising edge of SCLK. With $\overline{C S}$ low, data is clocked out of DOUT on the falling edge of SCLK. When $\overline{\mathrm{CS}}$ is high, activity on SCLK and DIN is ignored and DOUT is high impedance. |
| 11 | 8 | DIN | Serial Data Input. When $\overline{\mathrm{CS}}$ is low, data is clocked in on the rising edge of SCLK. When $\overline{\mathrm{CS}}$ is high, transitions on DIN are ignored. |
| 12 | 9 | SSTRB | Serial-Strobe Output. When using the internal clock, SSTRB rising edge transitions indicate that data is ready to be read from the device. When operating in external clock mode, SSTRB is always low. SSTRB does not tri-state, regardless of the state of $\overline{\mathrm{CS}}$, and therefore requires a dedicated I/O line. |
| 13 | 10 | SCLK | Serial Clock Input. When $\overline{\mathrm{CS}}$ is low, transitions on SCLK clock data into DIN and out of DOUT. When $\overline{\mathrm{CS}}$ is high, transitions on SCLK are ignored. |
| 14 | 11 | DOUT | Serial Data Output. When $\overline{\mathrm{CS}}$ is low, data is clocked out of DOUT with each falling SCLK transition. When $\overline{\mathrm{CS}}$ is high, DOUT is high impedance. |
| 15 | 12 | DGNDO | Digital I/O Ground. DGND, DGNDO, AGND3, AGND2, and AGND1 must be connected together. |
| 16 | 13 | DGND | Digital Ground. DGND, DGNDO, AGND3, AGND2, and AGND1 must be connected together. |
| 17 | 14 | DVDDO | Digital I/O Supply Voltage Input. Connect DVDDO to a +2.7 V to +5.25 V power-supply voltage. Bypass DVDDO to DGNDO with a $0.1 \mu \mathrm{~F}$ capacitor. |
| 18 | 15 | DVDD | Digital-Supply Voltage Input. Connect DVDD to $\mathrm{a}+4.75 \mathrm{~V}$ to +5.25 V power-supply voltage. Bypass DVDD to DGND with a $0.1 \mu \mathrm{~F}$ capacitor. |
| 19 | 16 | REFCAP | Bandgap-Voltage Bypass Node. For external reference operation, connect REFCAP to AVDD. For internal reference operation, bypass REFCAP with a $0.01 \mu \mathrm{~F}$ capacitor to AGND1 (VREFCAP $\approx 4.096 \mathrm{~V})$. |
| 20 | 17 | REF | Reference-Buffer Output/ADC Reference Input. For external reference operation, apply an external reference voltage from 3.800 V to 4.136 V to REF. For internal reference operation, bypassing REF with a $1 \mu \mathrm{~F}$ capacitor to AGND1 sets $\mathrm{V}_{\mathrm{REF}}=4.096 \mathrm{~V} \pm 1 \%$. |

## Detailed Description

The MAX1300／MAX1301 multirange，low－power，16－bit successive－approximation ADCs operate from a single +5 V supply and have a separate digital supply allowing digital interface with 2.7 V to 5.25 V systems．These 16 －bit ADCs have internal track－and－hold（T／H）circuitry that supports single－ended and fully differential inputs．For single－ended conversions，the valid analog input voltage range spans from -12 V below ground to +12 V above ground．The maximum allowable differential input volt－ age spans from -24 V to +24 V ．Data can be converted in a variety of software－programmable channel and data－ acquisition configurations．Microprocessor（ $\mu \mathrm{P}$ ）control is made easy through an SPI－／QSPI－／MICROWIRE－compati－ ble serial interface．

The MAX1300 has eight single－ended analog input channels or four differential channels（see the Block Diagram at the end of the data sheet）．The MAX1301 has four single－ended analog input channels or two dif－ ferential channels．Each analog input channel is inde－ pendently software programmable for seven single－ended input ranges（ 0 to $+6 \mathrm{~V},-6 \mathrm{~V}$ to 0,0 to $+12 \mathrm{~V},-12 \mathrm{~V}$ to $0, \pm 3 \mathrm{~V}, \pm 6 \mathrm{~V}$ ，and $\pm 12 \mathrm{~V}$ ）and three differ－ ential input ranges $( \pm 6 \mathrm{~V}, \pm 12 \mathrm{~V}$ ，and $\pm 24 \mathrm{~V})$ ． Additionally，all analog input channels are fault tolerant to $\pm 16.5 \mathrm{~V}$ ．A fault condition on an idle channel does not affect the conversion result of other channels．

## 8-/4-Channel, $\pm 12 V$ Multirange Inputs, Serial 16-Bit ADCs

#### Abstract

Power Supplies To maintain a low-noise environment, the MAX1300 and MAX1301 provide separate power supplies for each section of circuitry. Table 1 shows the four separate power supplies. Achieve optimal performance using separate AVDD1, AVDD2, DVDD, and DVDDO supplies. Alternatively, connect AVDD1, AVDD2, and DVDD together as close to the device as possible for a convenient power connection. Connect AGND1, AGND2, AGND3, DGND, and DGNDO together as close to the device as possible. Bypass each supply to the corresponding ground using a $0.1 \mu \mathrm{~F}$ capacitor (Table 1). If significant low-frequency noise is present, add a $10 \mu \mathrm{~F}$ capacitor in parallel with the $0.1 \mu \mathrm{~F}$ bypass capacitor.

## Converter Operation

The MAX1300/MAX1301 ADCs feature a fully differential, successive-approximation register (SAR) conversion technique and an on-chip T/H block to convert voltage signals into a 16-bit digital result. Both singleended and differential configurations are supported with programmable unipolar and bipolar signal ranges.

## Track-and-Hold Circuitry

The MAX1300/MAX1301 feature a switched-capacitor T/H architecture that allows the analog input signal to be stored as charge on sampling capacitors. See Figures 2, 3 , and 4 for $\mathrm{T} / \mathrm{H}$ timing and the sampling instants for each operating mode. The MAX1300/MAX1301 analog input circuitry buffers the input signal from the sampling capacitors, resulting in a constant input impedance with varying input voltage (Figure 5).

Analog Input Circuitry Select differential or single-ended conversions using the associated analog input configuration byte (Table 2). The analog input signal source must be capable of driving the ADC's $17 \mathrm{k} \Omega$ input resistance (Figure 6).
Figure 6 shows the simplified analog input circuit. The analog inputs are $\pm 16.5 \mathrm{~V}$ fault tolerant and are protected by back-to-back diodes. The summing junction voltage, VSJ, is a function of the channel's input commonmode voltage:

$$
V_{S J}=\left(\frac{\mathrm{R} 1}{\mathrm{R} 1+\mathrm{R} 2}\right) \times 2.375 \mathrm{~V}+\left(1+\left(\frac{\mathrm{R} 1}{\mathrm{R} 1+\mathrm{R} 2}\right)\right) \times \mathrm{V}_{\mathrm{CM}}
$$

As a result, the analog input impedance is relatively constant over input voltage as shown in Figure 5.

Table 1. MAX1300/MAX1301 Power Supplies and Bypassing

| POWER <br> SUPPLY/GROUND | SUPPLY VOLTAGE <br> RANGE (V) | TYPICAL SUPPLY <br> CURRENT (mA) | CIRCUIT SECTION | BYPASSING |
| :---: | :---: | :---: | :--- | :---: |
| $\mathrm{DV}_{\mathrm{DDO}} / \mathrm{DGNDO}$ | 2.7 to 5.25 | 0.2 | Digital I/O | $0.1 \mu \mathrm{~F}$ to DGNDO |

Table 2. Analog Input Configuration Byte

| BIT NUMBER | NAME | DESCRIPTION |
| :---: | :---: | :---: |
| 7 | START | Start Bit. The first logic 1 after $\overline{\mathrm{CS}}$ goes low defines the beginning of the analog input configuration byte. |
| 6 | C2 | Channel-Select Bits. SEL[2:0] select the analog input channel to be configured (Tables 4 and 5). |
| 5 | C1 |  |
| 4 | C0 |  |
| 3 | DIF/̄GL | Differential or Single-Ended Configuration Bit. DIF/ $\overline{\text { SGL }}=0$ configures the selected analog input channel for single-ended operation. DIF/ $\overline{\mathrm{SGL}}=1$ configures the channel for differential operation. In single-ended mode, input voltages are measured between the selected input channel and AGND1, as shown in Table 4. In differential mode, the input voltages are measured between two input channels, as shown in Table 5. Be aware that changing DIF//SGL adjusts the FSR, as shown in Table 6. |
| 2 | R2 | Input-Range-Select Bits. $\mathrm{R}[2: 0]$ select the input voltage range, as shown in Table 6 and Figure 7. |
| 1 | R1 |  |
| 0 | R0 |  |

## 8-/4-Channel, $\pm 12 \mathrm{~V}$ Multirange Inputs, Serial 16-Bit ADCs

Figure 2. External Clock-Mode Conversion (Mode 0)

Single-ended conversions are internally referenced to AGND1 (Tables 3 and 4). In differential mode, IN+ and IN - are selected according to Tables 3 and 5 . When configuring differential channels, the differential pair follows the analog configuration byte for the positive channel. For example, to configure CH 2 and CH 3 for a $\pm 12 \mathrm{~V}$ differential conversion, set the CH 2 analog configuration byte for a differential conversion with the $\pm 12 \mathrm{~V}$ range (1010 1100). To initiate a conversion for the CH 2 and CH3 differential pair, issue the command 10100000.

## Analog Input Bandwidth

The MAX1300/MAX1301 input-tracking circuitry has a 2 MHz small-signal bandwidth. The 2 MHz input bandwidth makes it possible to digitize high-speed transient events. Harmonic distortion increases when digitizing signal frequencies above 15 kHz as shown in the THD and -SFDR vs. Input Frequency plot in the Typical Operating Characteristics.

## Analog Input Range and Fault Tolerance

Figure 7 illustrates the software-selectable single-ended analog input voltage range that produces a valid digital output. Each analog input channel can be independently programmed to one of seven single-ended input ranges by setting the R[2:0] control bits with DIF/SGL $=0$.

## 8-/4-Channel, $\pm 12 V$ Multirange Inputs, Serial 16-Bit ADCs

Figure 3. External Acquisition-Mode Conversion (Mode 1)

Figure 8 illustrates the software-selectable differential analog input voltage range that produces a valid digital output. Each analog input differential pair can be independently programmed to one of three differential input ranges by setting the $\mathrm{R}[2: 0]$ control bits with $\mathrm{DIF} / \overline{\mathrm{SGL}}=1$.
Regardless of the specified input voltage range and whether the channel is selected, each analog input is $\pm 16.5 \mathrm{~V}$ fault tolerant. The analog input fault protection is active whether the device is unpowered or powered.

Any voltage beyond FSR, but within the $\pm 16.5 \mathrm{~V}$ faulttolerant range, applied to an analog input results in a full-scale output voltage for that channel.
Clamping diodes with breakdown thresholds in excess of 16.5 V protect the MAX1300/MAX1301 analog inputs during ESD and other transient events (Figure 6). The clamping diodes do not conduct during normal device operation, nor do they limit the current during such transients. When operating in an environment with the potential for high-energy voltage and/or current transients, protect the MAX1300/MAX1301 externally.

## Differential Common-Mode Range

The MAX1300/MAX1301 differential common-mode range (VCMDR) must remain within -14 V to +10 V to obtain valid conversion results. The differential common-mode range is defined as:

$$
\mathrm{V}_{\mathrm{CMDR}}=\frac{\left(\mathrm{CH}_{-}+\right)+\left(\mathrm{CH}_{-}\right)}{2}
$$

In addition to the common-mode input voltage limitations, each individual analog input must be limited to $\pm 16.5 \mathrm{~V}$ with respect to AGND1.

The range-select bits $R[2: 0]$ in the analog input configuration bytes determine the full-scale range for the corresponding channel (Tables 2 and 6). Figures 9, 10, and 11 show the valid analog input voltage ranges for the MAX1300/MAX1301 when operating with FSR = $12 \mathrm{~V}, \mathrm{FSR}=24 \mathrm{~V}$, and $\mathrm{FSR}=48 \mathrm{~V}$, respectively. The shaded area contains the valid common-mode voltage ranges that support the entire FSR.

## 8-/4-Channel, $\pm 12 \mathrm{~V}$ Multirange Inputs, Serial 16-Bit ADCs

Figure 7. Single-Ended Input Voltage Ranges
Digital Interface
The MAX1300/MAX1301 feature a serial interface that is compatible with SPI/QSPI and MICROWIRE devices. DIN, DOUT, SCLK, $\overline{C S}$, and SSTRB facilitate bidirectional communication between the MAX1300/MAX1301 and the master at SCLK rates up to 10 MHz (internal clock mode, mode 2), 3.67 MHz (external clock mode, mode 0), or 4.39 MHz (external acquisition mode, mode 1). The master, typically a microcontroller, should use the $\mathrm{CPOL}=0, \mathrm{CPHA}=0, \mathrm{SPI}$ transfer format, as shown in the timing diagrams of Figures 2, 3, and 4.
The digital interface is used to:

- Select single-ended or true-differential input channel configurations
- Select the unipolar or bipolar input range
- Select the mode of operation:

External clock (mode 0)
External acquisition (mode 1)
Internal clock (mode 2)
Reset (mode 4)
Partial power-down (mode 6)
Full power-down (mode 7)

- Initiate conversions and read results

Figure 8. Differential Input Voltage Ranges
Chip Select ( $\overline{C S}$ )
$\overline{\mathrm{CS}}$ enables communication with the MAX1300/MAX1301. When $\overline{\mathrm{CS}}$ is low, data is clocked into the device from DIN on the rising edge of SCLK and data is clocked out of DOUT on the falling edge of SCLK. When $\overline{\mathrm{CS}}$ is high, activity on SCLK and DIN is ignored and DOUT is high impedance allowing DOUT to be shared with other peripherals. SSTRB is never high impedance and therefore cannot be shared with other peripherals.

Serial Strobe Output (SSTRB)
As shown in Figures 3 and 4, the SSTRB transitions high to indicate that the ADC has completed a conversion and results are ready to be read by the master. SSTRB remains low in the external clock mode (Figure 2) and consequently may be left unconnected. SSTRB is driven high or low regardless of the state of $\overline{\mathrm{CS}}$, therefore SSTRB cannot be shared with other peripherals.

## 8-/4-Channel, $\pm 12 \mathrm{~V}$ Multirange Inputs, Serial 16-Bit ADCs

Figure 9. Common-Mode Voltage vs. Input Voltage (FSR = 12V)

Figure 11. Common-Mode Voltage vs. Input Voltage (FSR = 48V)

## Start Bit

Communication with the MAX1300/MAX1301 is accomplished using the three input data word formats shown in Table 3. Each input data word begins with a start bit. The start bit is defined as the first high bit clocked into DIN with $\overline{\mathrm{CS}}$ low when any of the following are true:

- Data conversion is not in process and all data from the previous conversion has clocked out of DOUT.
- The device is configured for operation in external clock mode (mode 0) and previous conversion-result bits B15-B3 have clocked out of DOUT.
- The device is configured for operation in external acquisition mode (mode 1) and previous conversionresult bits B15-B7 have clocked out of DOUT.
- The device is configured for operation in internal clock mode, (mode 2) and previous conversionresult bits B15-B4 have clocked out of DOUT.

Figure 10. Common-Mode Voltage vs. Input Voltage (FSR = 24V)

## Output Data Format

Output data is clocked out of DOUT in offset binary format on the falling edge of SCLK, MSB first (B15). For output binary codes, see the Transfer Function section and Figures 12, 13, and 14.

Configuring Analog Inputs
Each analog input has two configurable parameters:

- Single-ended or true-differential input
- Input voltage range

These parameters are configured using the analog input configuration byte as shown in Table 2. Each analog input has a dedicated register to store its input configuration information. The timing diagram of Figure 15 shows how to write to the analog input configuration registers. Figure 16 shows DOUT and SSTRB timing.

## Transfer Function

An ADC's transfer function defines the relationship between the analog input voltage and the digital output code. Figures 12, 13, and 14 show the MAX1300/ MAX1301 transfer functions. The transfer function is determined by the following characteristics:

- Analog input voltage range
- Single-ended or differential configuration
- Reference voltage

The axes of an ADC transfer function are typically in least significant bits (LSBs). For the MAX1300/MAX1301, an LSB is calculated using the following equation:

$$
1 \mathrm{LSB}=\frac{\mathrm{FSR} \times \mathrm{V}_{\mathrm{REF}}}{2^{\mathrm{N}} \times 4.096 \mathrm{~V}}
$$

where $N$ is the number of bits $(N=16)$ and FSR is the full-scale range (see Figures 7 and 8).

## 8-/4-Channel, $\pm 12 \mathrm{~V}$ Multirange Inputs, Serial 16-Bit ADCs

Figure 12. Ideal Bipolar Transfer Function, Single-Ended or Differential Input

Figure 14. Ideal Unipolar Transfer Function, Single-Ended Input, 0 to + FSR

## Mode Control

The MAX1300/MAX1301 contain one byte-wide modecontrol register. The timing diagram of Figure 15 shows how to use the mode-control byte, and the mode-control byte format is shown in Table 7. The mode-control byte is used to select the conversion method and to control the power modes of the MAX1300/MAX1301.

Figure 13. Ideal Unipolar Transfer Function, Single-Ended Input, -FSR to 0

## Selecting the Conversion Method

The conversion method is selected using the mode-control byte (see the Mode Control section), and the conversion is initiated using a conversion-start command (Table 3, and Figures 2, 3, and 4).The MAX1300/MAX1301 convert analog signals to digital data using one of three methods:

- External Clock Mode, Mode 0 (Figure 2)
- Highest maximum throughput (see the Electrical Characteristics table)
- User controls the sample instant
- $\overline{\mathrm{CS}}$ remains low during the conversion
- User supplies SCLK throughout the ADC conversion and reads data at DOUT
- External Acquisition Mode, Mode 1 (Figure 3)
- Lowest maximum throughput (see the Electrical Characteristics table)
- User controls the sample instant
- User supplies two bytes of SCLK, then drives $\overline{\mathrm{CS}}$ high to relieve processor load while the ADC converts
- After SSTRB transitions high, the user supplies two bytes of SCLK and reads data at DOUT
- Internal Clock Mode, Mode 2 (Figure 4)
- High maximum throughput (see the Electrical Characteristics table)
- The internal clock controls the sampling instant

## 8-/4-Channel, $\pm 12 \mathrm{~V}$ Multirange Inputs, Serial 16-Bit ADCs

Figure 15. Analog Input Configuration Byte and Mode-Control Byte Timing
External Clock Mode (Mode 0)
The MAX1300/MAX1301's fastest maximum throughput rate is achieved operating in external clock mode. SCLK controls both the acquisition and conversion of the analog signal, facilitating precise control over when the analog signal is captured. The analog input sampling instant is at the falling edge of the 14th SCLK (Figure 2).
Since SCLK drives the conversion in external clock mode, the SCLK frequency should remain constant while the conversion is clocked. The minimum SCLK frequency prevents droop in the internal sampling capacitor voltages during conversion.
SSTRB remains low in the external clock mode, and as a result may be left unconnected if the MAX1300/ MAX1301 will always be used in the external clock mode.

Figure 16. DOUT and SSTRB Timing

- User supplies one byte of SCLK, then drives $\overline{\mathrm{CS}}$ high to relieve processor load while the ADC converts
- After SSTRB transitions high, the user supplies two bytes of SCLK and reads data at DOUT

Table 7. Mode-Control Byte

| BIT NUMBER | BIT NAME |  |
| :---: | :---: | :--- |
| 7 | START | Start Bit. The first logic 1 after $\overline{\mathrm{CS}}$ goes low defines the beginning of the mode-control byte. |
| 6 | M2 |  |
| 5 | M1 |  |
| 4 | M0 |  |
| 3 | 1 | Bit 3 must be a logic 1 for the mode-control byte. |
| 2 | 0 | Bit 2 must be a logic 0 for the mode-control byte. |
| 1 | 0 | Bit 1 must be a logic 0 for the mode-control byte. |
| 0 | 0 | Bit 0 must be a logic 0 for the mode-control byte. |

## 8-/4-Channel, $\pm 12 V$ Multirange Inputs, Serial 16-Bit ADCs

Table 8. Mode-Control Bits M[2:0]

| M2 | M1 | M0 |  |
| :---: | :---: | :---: | :--- |
| 0 | 0 | 0 | External Clock (DEFAULT) |
| 0 | 0 | 1 | External Acquisition |
| 0 | 1 | 0 | Internal Clock |
| 0 | 1 | 1 | Reserved |
| 1 | 0 | 0 | Reset |
| 1 | 0 | 1 | Reserved |
| 1 | 1 | 0 | Partial Power-Down |
| 1 | 1 | 1 | Full Power-Down |

External Acquisition Mode (Mode 1)
The slowest maximum throughput rate is achieved with the external acquisition method. SCLK controls the acquisition of the analog signal in external acquisition mode, facilitating precise control over when the analog signal is captured. The internal clock controls the conversion of the analog input voltage. The analog input sampling instant is at the falling edge of the 16th SCLK (Figure 3).
For the external acquisition mode, $\overline{\mathrm{CS}}$ must remain low for the first 15 clock cycles and the rise on or after the falling edge of the 16 th SCLK cycle as shown in Figure 3. For optimal performance, idle DIN and SCLK during the conversion. With careful board layout, transitions at DIN and SCLK during the conversion have a minimal impact on the conversion result.
After the conversion is complete, SSTRB asserts high and $\overline{\mathrm{CS}}$ can be brought low to read the conversion result. SSTRB returns low on the rising SCLK edge of the subsequent start bit.

## Internal Clock Mode (Mode 2)

In internal clock mode, the internal clock controls both acquisition and conversion of the analog signal. The internal clock starts approximately 100 ns to 400 ns after the falling edge of the eighth SCLK and has a rate of about 4.5 MHz . The analog input sampling instant occurs at the falling edge of the 11th internal clock signal (Figure 4).
For the internal clock mode, $\overline{\mathrm{CS}}$ must remain low for the first seven SCLK cycles and then rise on or after the falling edge of the eighth SCLK cycle. After the conversion is complete, SSTRB asserts high and $\overline{\mathrm{CS}}$ can be brought low to read the conversion result. SSTRB returns low on the rising SCLK edge of the subsequent start bit.

Reset (Mode 4)
As shown in Table 8, set $\mathrm{M}[2: 0]=100$ to reset the MAX1300/MAX1301 to its default conditions. The default conditions are full power operation with each channel configured for $\pm 12 \mathrm{~V}$, bipolar, single-ended conversions using external clock mode (mode 0).

Partial Power-Down Mode (Mode 6) As shown in Table 8, when M[2:0] = 110, the device enters partial power-down mode. In partial powerdown, all analog portions of the device are powered down except for the reference voltage generator and bias supplies.
To exit partial power-down, change the mode by issuing one of the following mode-control bytes (see the Mode Control section):

- External-Clock-Mode Control Byte
- External-Acquisition-Mode Control Byte
- Internal-Clock-Mode Control Byte
- Reset Byte
- Full Power-Down-Mode Control Byte

This prevents the MAX1300/MAX1301 from inadvertently exiting partial power-down mode because of a $\overline{\mathrm{CS}}$ glitch in a noisy digital environment.

## Full Power-Down Mode (Mode 7)

When $\mathrm{M}[2: 0]=111$, the device enters full power-down mode and the total supply current falls to $1 \mu \mathrm{~A}$ (typ). In full power-down, all analog portions of the device are powered down. When using the internal reference, upon exiting full power-down mode, allow 10 ms for the internal reference voltage to stabilize prior to initiating a conversion.
To exit full power-down, change the mode by issuing one of the following mode-control bytes (see the Mode Control section):

- External-Clock-Mode Control Byte

# 8-/4-Channel, $\pm 12 \mathrm{~V}$ Multirange Inputs, Serial 16-Bit ADCs 

- External-Acquisition-Mode Control Byte
- Internal-Clock-Mode Control Byte
- Reset Byte
- Partial Power-Down-Mode Control Byte

This prevents the MAX1300/MAX1301 from inadvertently exiting full power-down mode because of a $\overline{\mathrm{CS}}$ glitch in a noisy digital environment.

Power-On Reset
The MAX1300/MAX1301 power up in normal operation configured for external clock mode with all circuitry active (Tables 7 and 8). Each analog input channel (CHO-CH7) is set for single-ended conversions with a $\pm 12 \mathrm{~V}$ bipolar input range (Table 6).
Allow the power supplies to stabilize after power-up. Do not initiate any conversions until the power supplies have stabilized. Additionally, allow 10 ms for the internal reference to stabilize when $\mathrm{CREF}=1.0 \mu \mathrm{~F}$ and CRECAP $=0.1 \mu \mathrm{~F}$. Larger reference capacitors require longer stabilization times.

## Internal or External Reference

The MAX1300/MAX1301 operate with either an internal or external reference. The reference voltage impacts the ADC's FSR (Figures 12, 13, and 14). An external reference is recommended if more accuracy is required than the internal reference provides, and/or multiple converters require the same reference voltage.

## Internal Reference

The MAX1300/MAX1301 contain an internal 4.096V bandgap reference. This bandgap reference is connected to REFCAP through a nominal $5 \mathrm{k} \Omega$ resistor (Figure 17). The voltage at REFCAP is buffered creating 4.096 V at

Figure 17. Internal Reference Operation

REF. When using the internal reference, bypass REFCAP with a $0.1 \mu \mathrm{~F}$ or greater capacitor to AGND1 and bypass REF with a $1.0 \mu \mathrm{~F}$ or greater capacitor to AGND1.

External Reference
For external reference operation, disable the internal reference and reference buffer by connecting REFCAP to $A V_{D D 1}$. With $A V_{D D 1}$ connected to REFCAP, REF becomes a high-impedance input and accepts an external reference voltage. The MAX1300/MAX1301 external reference current varies depending on the applied reference voltage and the operating mode (see the External Reference Input Current vs. External Reference Input Voltage in the Typical Operating Characteristics).

## Applications Information

Noise Reduction
Additional samples can be taken and averaged (over-
conversion results. The square root of the number of samples determines the improvement in performance. For example, with $2 / 3$ LSBRMS (4LSBP-P) transition noise, $16\left(4^{2}=16\right)$ samples must be taken to reduce the noise to 1LSBp-p.

## Interface with 0 to 10V Signals

In industrial control applications, 0 to 10 V signaling is common. For 0 to 10 V applications, configure the selected MAX1300/MAX1301 input channel for the single-ended 0 to 12 V input range $(\mathrm{R}[2: 0]=110$, Table 6$)$. The 0 to 12 V range accommodates 0 to 10 V where the signals saturate at approximately 12 V if out of range.

## Interface with 4-20mA Signals

Figure 19 illustrates a simple interface between the MAX1300/MAX1301 and a 4-20mA signal. 4-20mA signaling can be used as a binary switch (4mA represents a logic-low signal, 20 mA represents a logic-high signal), or for precision communication where currents between 4 mA and 20 mA represent intermediate analog data. For binary switch applications, connect the 4-20mA signal to the MAX1300/MAX1301 with a resistor to ground. For example, a $250 \Omega$ resistor converts the $4-20 \mathrm{~mA}$ signal to a 1 V to 5 V signal. Adjust the resistor value so the parallel combination of the resistor and the MAX1300/MAX1301 source impedance is $250 \Omega$. In this application, select the single-ended 0 to 6 V range $(\mathrm{R}[2: 0]=011$, Table 6$)$. For applications that require precision measurements of continuous analog currents between 4 mA and 20 mA , use a buffer to prevent the MAX1300/MAX1301 input from diverting current from the $4-20 \mathrm{~mA}$ signal.

## 8-/4-Channel, $\pm 12 V$ Multirange Inputs, Serial 16-Bit ADCs

Figure 18. External Reference Operation

## Bridge Application

The MAX1300/MAX1301 convert 1 kHz signals more accurately than a similar sigma-delta converter that might be considered in bridge applications. The input impedance of the MAX1300, in combination with the cur-rent-limiting resistors, can affect the gain of the MAX1300. In many applications this error is acceptable, but for applications that cannot tolerate this error, the MAX1300 inputs can be buffered (Figure 20). Connect the bridge to a low-offset differential amplifier and then the true-differential inputs of the MAX1300/MAX1301. Larger excitation voltages take advantage of more of the $\pm 3 \mathrm{~V}$ differential input voltage range. Select an input voltage range that matches the amplifier output. Be aware of the amplifier offset and offset-drift errors when selecting an appropriate amplifier.

## Dynamically Adjusting the Input Range

Software control of each channel's analog input range and the unipolar endpoint overlap specification make it possible for the user to change the input range for a channel dynamically and improve performance in some applications. Changing the input range results in a small LSB step-size over a wider output voltage range. For example, by switching between a -6 V to OV range and a 0 to 6 V range, an LSB is

$$
\frac{6 \mathrm{~V} \times \mathrm{V}_{\text {REF }}}{65,536 \times 4.096}
$$

but the input voltage range effectively spans from -6 V to $+6 \mathrm{~V}(F S R=12 \mathrm{~V})$.

## Layout, Grounding, and Bypassing

Careful PC board layout is essential for best system performance. Boards should have separate analog and digital ground planes and ensure that digital and analog signals are separated from each other. Do not run analog and digital (especially clock) lines parallel to one another, or digital lines underneath the device package.
Figure 1 shows the recommended system ground connections. Establish an analog ground point at AGND1 and a digital ground point at DGND. Connect all analog grounds to the star analog ground. Connect the digital grounds to the star digital ground. Connect the digital ground plane to the analog ground plane at one point. For lowest noise operation, make the ground return to the star ground's power-supply low impedance and as short as possible.
High-frequency noise in the AVDD1 power supply degrades the ADC's high-speed comparator performance. Bypass AVDD1 to AGND1 with a $0.1 \mu \mathrm{~F}$ ceramic surface-mount capacitor. Make bypass capacitor connections as short as possible.

## Parameter Definitions <br> Integral Nonlinearity (INL)

INL is the deviation of the values on an actual transfer function from a straight line. This straight line is either a best straight-line fit or a line drawn between the endpoints of the transfer function once offset and gain errors have been nullified. The MAX1300/MAX1301 INL is measured using the endpoint method.

## 8-/4-Channel, $\pm 12 \mathrm{~V}$ Multirange Inputs, Serial 16-Bit ADCs

Figure 19. 4-20mA Application

Figure 20. Bridge Application

Channel-to-Channel Isolation
Channel-to-channel isolation indicates how well each analog input is isolated from the others. The channel-tochannel isolation for these devices is measured by applying a near full-scale magnitude 5 kHz sine wave to the selected analog input channel while applying an equal magnitude sine wave of a different frequency to all unselected channels. An FFT of the selected channel output is used to determine the ratio of the magnitudes of the signal applied to the unselected channels and the 5 kHz signal applied to the selected analog input channel. This ratio is reported, in dB , as channel-to-channel isolation.

DNL is the difference between an actual step width and the ideal value of 1 LSB . A DNL error specification of greater than -1 LSB guarantees no missing codes and a monotonic transfer function.

Transition Noise
Transition noise is the amount of noise that appears at a code transition on the ADC transfer function. Conversions performed with the analog input right at the code transition can result in code flickering in the LSBs.

## Unipolar Offset Error -FSR to OV

When a zero-scale analog input voltage is applied to the converter inputs, the digital output is all ones (0xFFFFF). Ideally, the transition from 0xFFFF to OxFFFE occurs at AGND1-0.5 LSB. Unipolar offset error is the amount of deviation between the measured zero-scale transition point and the ideal zero-scale transition point, with all untested channels grounded.

OV to +FSR
When a zero-scale analog input voltage is applied to the converter inputs, the digital output is all zeros (0x0000). Ideally, the transition from 0x0000 to 0x0001 occurs at AGND1 + 0.5 LSB. Unipolar offset error is the amount of deviation between the measured zero-scale transition point and the ideal zero-scale transition point, with all untested channels grounded.

## Bipolar Offset Error

When a zero-scale analog input voltage is applied to the converter inputs, the digital output is a one followed by all zeros (0x8000). Ideally, the transition from 0x7FFF to $0 \times 8000$ occurs at ( $2^{\mathrm{N}-1}-0.5$ )LSB. Bipolar offset error is the amount of deviation between the measured midscale transition point and the ideal midscale transition point, with untested channels grounded.

## Gain Error

When a positive full-scale voltage is applied to the converter inputs, the digital output is all ones (0xFFFFF). The transition from 0xFFFE to 0xFFFF occurs at 1.5 LSB below full scale. Gain error is the amount of deviation between the measured full-scale transition point and the ideal full-scale transition point with the offset error removed and all untested channels grounded.

## Unipolar Endpoint Overlap

Unipolar endpoint overlap is the change in offset when switching between complementary input voltage ranges. For example, the difference between the voltage that results in a 0xFFFF output in the -6 V to 0 V input voltage range and the voltage that results in a $0 \times 0000$ output in the 0 to +6 V input voltage range is the unipolar endpoint overlap. The unipolar endpoint overlap is positive for the MAX1300/MAX1301, preventing loss of signal or a dead zone when switching between adjacent analog input voltage ranges.

## Small-Signal Bandwidth

A 100 mV P-p sine wave is applied to the ADC, and the input frequency is then swept up to the point where the amplitude of the digitized conversion result has decreased by $-3 d B$.

Full-Power Bandwidth
A 95\% of full-scale sine wave is applied to the ADC, and the input frequency is then swept up to the point where the amplitude of the digitized conversion result has decreased by -3dB.

## Common-Mode Rejection Ratio (CMRR)

CMRR is the ability of a device to reject a signal that is "common" to or applied to both input terminals. The common-mode signal can be either an AC or a DC signal or a combination of the two. CMR is expressed in decibels. Common-mode rejection ratio is the ratio of the differential signal gain to the common-mode signal gain. CMRR applies only to differential operation.

## Power-Supply Rejection Ratio (PSRR)

PSRR is the ratio of the output-voltage shift to the power-supply-voltage shift for a fixed input voltage. For the MAX1300/MAX1301, AVDD1 can vary from 4.75V to 5.25 V . PSRR is expressed in decibels and is calculated using the following equation:

$$
\mathrm{PSRR}[\mathrm{~dB}]=20 \times \log \left(\frac{5.25 \mathrm{~V}-4.75 \mathrm{~V}}{\mathrm{~V}_{\mathrm{OUT}}(5.25 \mathrm{~V})-\mathrm{V}_{\mathrm{OUT}}(4.75 \mathrm{~V})}\right)
$$

For the MAX1300/MAX1301, PSRR is tested in bipolar operation with the analog inputs grounded.

## Aperture Jitter

Aperture jitter, taJ, is the statistical distribution of the variation in the sampling instant (Figure 21).

## Aperture Delay

Aperture delay, tAD, is the time from the falling edge of SCLK to the sampling instant (Figure 21).

## Signal-to-Noise Ratio (SNR)

SNR is computed by taking the ratio of the RMS signal to the RMS noise. RMS noise includes all spectral components to the Nyquist frequency excluding the fundamental, the first five harmonics, and the DC offset.

## Signal-to-Noise Plus Distortion (SINAD)

SINAD is computed by taking the ratio of the RMS signal to the RMS noise plus distortion. RMS noise plus distortion includes all spectral components to the Nyquist frequency excluding the fundamental and the DC offset.

$$
\operatorname{SINAD}(\mathrm{dB})=20 \times \log \left(\frac{\text { Signal }_{\mathrm{RMS}}}{\text { Noise }_{\mathrm{RMS}}}\right)
$$

## 8-/4-Channel, $\pm 12 V$ Multirange Inputs, Serial 16-Bit ADCs

## Effective Number of Bits (ENOB)

ENOB indicates the global accuracy of an ADC at a specific input frequency and sampling rate. With an input range equal to the ADC's full-scale range, calculate the ENOB as follows:

$$
\mathrm{ENOB}=\left(\frac{\mathrm{SINAD}-1.76}{6.02}\right)
$$

Total Harmonic Distortion (THD)
For the MAX1300/MAX1301, THD is the ratio of the RMS sum of the input signal's first four harmonic components to the fundamental itself. This is expressed as:

$$
\mathrm{THD}=20 \times \log \left(\frac{\sqrt{V_{2}^{2}+V_{3}^{2}+V_{4}^{2}+V_{5}^{2}}}{V_{1}}\right)
$$

Figure 21. Aperture Diagram
where $\mathrm{V}_{1}$ is the fundamental amplitude, and $\mathrm{V}_{2}$ through $V_{5}$ are the amplitudes of the 2nd- through 5th-order harmonic components.

Spurious-Free Dynamic Range (SFDR)
SFDR is the ratio of RMS amplitude of the fundamental (maximum signal component) to the RMS value of the next-largest spectral component.
