## General Description

The MIC4426/4427/4428 family are highly-reliable dual lowside MOSFET drivers fabricated on a BiCMOS/DMOS process for low power consumption and high efficiency. These drivers translate TTL or CMOS input logic levels to output voltage levels that swing within 25 mV of the positive supply or ground. Comparable bipolar devices are capable of swinging only to within 1V of the supply. The MIC4426/7/8 is available in three configurations: dual inverting, dual noninverting, and one inverting plus one noninverting output.
The MIC4426/4427/4428 are pin-compatible replacements for the MIC426/427/428 and MIC1426/1427/1428 with improved electrical performance and rugged design (Refer to the Device Replacement lists on the following page). They can withstand up to 500 mA of reverse current (either polarity) without latching and up to 5 V noise spikes (either polarity) on ground pins.
Primarily intended for driving power MOSFETs, MIC4426/7/8 drivers are suitable for driving other loads (capacitive, resistive, or inductive) which require low-impedance, high peak current, and fast switching time. Other applications include driving heavily loaded clock lines, coaxial cables, or piezoelectric transducers. The only load limitation is that total driver power dissipation must not exceed the limits of the package.

## Features

- Bipolar/CMOS/DMOS construction
- Latch-up protection to $>500 \mathrm{~mA}$ reverse current
- 1.5A-peak output current
- 4.5 V to 18 V operating range
- Low quiescent supply current 4 mA at logic 1 input $400 \mu \mathrm{~A}$ at logic 0 input
- Switches 1000 pF in 25 ns
- Matched rise and rall times
- $7 \Omega$ output impedance
- <40ns typical delay
- Logic-input threshold independent of supply voltage
- Logic-input protection to -5 V
- $6 p F$ typical equivalent input capacitance
- 25 mV max. output offset from supply or ground
- Replaces MIC426/427/428 and MIC1426/1427/1428
- Dual inverting, dual noninverting, and inverting/ noninverting configurations
- ESD protection

## Applications

- MOSFET driver
- Clock line driver
- Coax cable driver
- Piezoelectic transducer driver

## Electrical Characteristics

## Applications Information

## Supply Bypassing

Large currents are required to charge and discharge large capacitive loads quickly. For example, changing a 1000 pF load by 16 V in 25 ns requires 0.8 A from the supply input.
To guarantee low supply impedance over a wide frequency range, parallel capacitors are recommended for power supply bypassing. Low-inductance ceramic MLC capacitors with short lead lengths ( $<0.5$ ") should be used. A $1.0 \mu \mathrm{~F}$ film capacitor in parallel with one or two $0.1 \mu \mathrm{~F}$ ceramic MLC capacitors normally provides adequate bypassing.

## Grounding

When using the inverting drivers in the MIC4426 or MIC4428, individual ground returns for the input and output circuits or a ground plane are recommended for optimum switching speed. The voltage drop that occurs between the driver's ground and the input signal ground, during normal high-current switching, will behave as negative feedback and degrade switching speed.

## Control Input

Unused driver inputs must be connected to logic high (which can be $V_{S}$ ) or ground. For the lowest quiescent current ( $<500 \mu \mathrm{~A}$ ), connect unused inputs to ground. A logic-high signal will cause the driver to draw up to 9 mA .
The drivers are designed with 100 mV of control input hysteresis. This provides clean transitions and minimizes output stage current spikes when changing states. The control input voltage threshold is approximately 1.5 V . The control input recognizes 1.5 V up to $\mathrm{V}_{\mathrm{S}}$ as a logic high and draws less than $1 \mu \mathrm{~A}$ within this range.
The MIC4426/7/8 drives the TL494, SG1526/7, MIC38C42, TSC170 and similar switch-mode power supply integrated circuits.

## Power Dissipation

Power dissipation should be calculated to make sure that the driver is not operated beyond its thermal ratings. Quiescent power dissipation is negligible. A practical value for total power dissipation is the sum of the dissipation caused by the load and the transition power dissipation ( $\mathrm{P}_{\mathrm{L}}+\mathrm{P}_{\mathrm{T}}$ ).

## Load Dissipation

Power dissipation caused by continuous load current (when driving a resistive load) through the driver's output resistance is:

$$
P_{L}=I_{L}^{2} R_{O}
$$

For capacitive loads, the dissipation in the driver is:

$$
P_{L}=f C_{L} V_{S}^{2}
$$

## Transition Dissipation

In applications switching at a high frequency, transition power dissipation can be significant. This occurs during switching transitions when the P-channel and N -channel output FETs are both conducting for the brief moment when one is turning on and the other is turning off.

$$
P_{T}=2 f V_{S} Q
$$

Charge $(Q)$ is read from the following graph:

Crossover Energy Loss per Transition

## Package Information
