

# **FLASH MEMORY**

# MT28F320A18

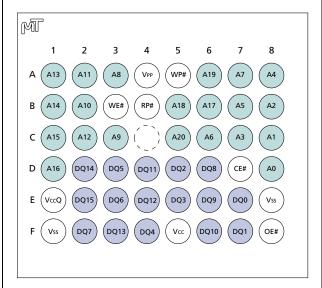

Low Voltage, Extended Temperature 0.15µm Process Technology

### **FEATURES**

- 32Mb block architecture
   Seventy-one erasable blocks:
   Eight 4K-word parameter blocks
   Sixty-three 32K-word main memory blocks
- VCC, VCCQ, VPP voltages\*

   1.65V (MIN), 1.95V (MAX) VCC, VCCQ
   0.9V (MIN), 1.95V (MAX) VPP (in-system PROGRAM/ERASE)
   12V ±5% (HV) VPP tolerant (factory programming compatibility)
- Random access time: 70ns @ 1.65V VCC
- Low power consumption (VCC = 1.8V)
   Asynchronous Read < 18mA
   Write/Erase < 40mA (MAX)
   Standby < 50μA (MAX)
   Automatic power saving feature (APS)</li>
- Enhanced write and erase suspend options ERASE-SUSPEND-to-READ PROGRAM-SUSPEND-to-READ ERASE-SUSPEND-to-PROGRAM
- Dual 64-bit chip protection registers for security purposes
- Cross-compatible command support Extended command set Common flash interface
- PROGRAM/ERASE cycle
   100,000 WRITE/ERASE cycles per block
   (VPP = VPP1)

<sup>\*</sup>An extended voltage range of 1.65V–2.20V for Vcc and VccQ, and 0.9V–2.20V for Vpp is available upon request. A voltage range of 1.42V–1.60V for VccQ is also available upon request.

### **GENERAL DESCRIPTION**

The MT28F320A18 is a nonvolatile electrically block-erasable (Flash) memory containing eight 4K-word parameter blocks and sixty-three 32K-word main blocks.

The MT28F320A18 allows soft protection for blocks, as read only, by configuring soft protection registers with dedicated command sequences. For security purposes, a 128-bit chip protection register is provided.

The embedded WORD WRITE and BLOCK ERASE functions are fully automated by an on-chip write state machine (WSM). An on-chip status register can be used to monitor the WSM status and to determine the progress of the PROGRAM/ERASE task.

The ERASE/PROGRAM SUSPEND functionality allows compatibility with existing EEPROM emulation software packages.

The device is manufactured using 0.15µm process technology.

Please refer to Micron's Web site (www.micron.com/flash) for the latest data sheet.

# ARCHITECTURE AND MEMORY ORGANIZATION

The MT28F320A18 contains eight 4K-word parameter blocks and sixty-three 32K-word main blocks.

Figure 2 and Figure 3 show the bottom and top memory organizations for the 32Mb device.

### **DEVICE MARKING**

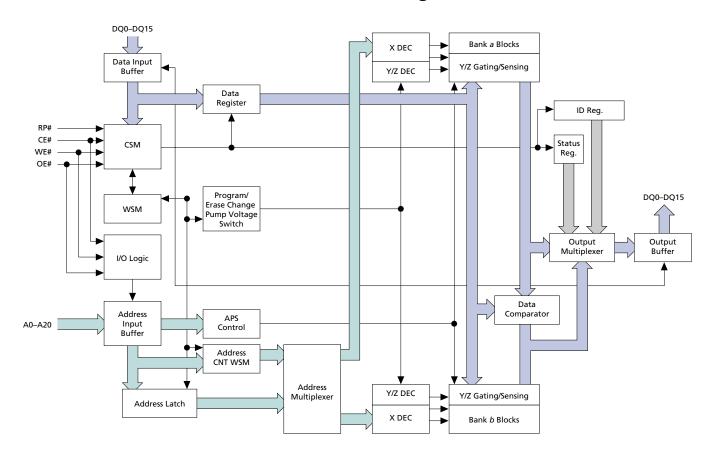

Due to the size of the package, Micron's standard part number is not printed on the top of each device. Instead, an abbreviated device mark comprised of a five-digit alphanumeric code is used. The abbreviated device marks are cross referenced to Micron part numbers in Table 1.

**Table 1: Cross Reference for Abbreviated Device Marks** 

PART NUMBER	PRODUCT MARKING	SAMPLE MARKING	MECHANICAL SAMPLE MARKING
MT28F320A18FF-70 BET	FW722	FX722	FY722
MT28F320A18FF-70 TET	FW723	FX723	FY723

# **Functional Block Diagram**

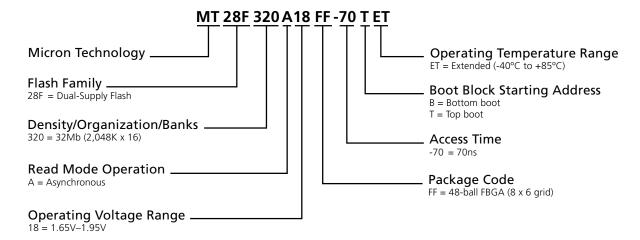

### PART NUMBERING INFORMATION

Micron's low-power devices are available with several different combinations of features (see Figure 1).

Valid combinations of features and their corresponding part numbers are listed in Table 2.

**Figure 1: Part Number Chart**

# **BALL DESCRIPTIONS**

48-BALL FBGA NUMBERS	SYMBOL	TYPE	DESCRIPTION
D8, C8, B8, A8, C7, B7, A7, C6, B6, A6, C5, B5, C3, A3, C2, B2, A2, D1, C1, B1, A1	A0-A20	Input	Address Inputs: Inputs for the address during READ and WRITE operations. Addresses are internally latched during WRITE and ERASE cycles.
D7	CE#	Input	Chip Enable: Activates the device when LOW. When CE# is HIGH, the device is disabled and goes into standby power mode.
F8	OE#	Input	Output Enable: Enables the outputs buffer when LOW. When OE# is HIGH, the output buffers are disabled.
В3	WE#	Input	Write Enable: Determines if a given cycle is a WRITE cycle. If WE# is LOW, the cycle is either a WRITE to the command state machine (CSM) or to the memory array.
В4	RP#	Input	Reset: When RP# is a logic LOW, the device is in reset mode, which drives the outputs to High-Z and resets the write state machine (WSM). When RP# is at logic HIGH, the device is in standard operation. When RP# transitions from logic LOW to logic HIGH, the device resets all blocks to locked and defaults to the read array mode.
A5	WP#	Input	Write Protect: Controls the lock down function of the flexible locking feature.
E7, F7, D5, E5, F4, D3, E3, F2, D6, E6, F6, D4, E4, F3, D2, E2	DQ0-DQ15	Input/ Output	Data Inputs/Outputs: Inputs array data on the second CE# and WE# cycle during PROGRAM command. Inputs commands to the command user interface when CE# and WE# are active.
A4	VPP	Supply	Block Erase and Program Power Supply: [VPP1 = 0.9V-1.95V or VPP2 = 11.4V-12.6V]. A valid voltage on this contact allows block erase or data programming. Memory contents cannot be altered when VPP \( \leq \text{VPPLK}. \) Block erase and program at invalid VPP voltages should not be attempted. It provides factory programming compatibility when driven to 11.4V-12.6V
F5	Vcc	Supply	Device Power Supply: [1.65V–1.95V] Supplies power for device operation.
E1	VccQ	Supply	I/O Power Supply: [1.65V–1.95V] Supplies power for input/output buffers. This input should be tied directly to Vcc.
E8, F1	Vss	Supply	Do not float any ground ball.
C4	NC	-	Internally not connected.

### **COMMAND STATE MACHINE**

Commands are issued to the command state machine (CSM) using standard microprocessor write timings. The CSM acts as an interface between external microprocessors and the internal write state machine (WSM). The available commands are listed in Table 3, their definitions are given in Table 4 and their descriptions in Table 5. Program and erase algorithms are automated by an on-chip WSM. Table 6 shows the CSM transition states.

Once a valid PROGRAM/ERASE command is entered, the WSM executes the appropriate algorithm, which generates the necessary timing signals to control the device internally and accomplish the requested operation. A command is valid only if the exact sequence of WRITE cycles is completed. After the WSM completes its task, the WSM status bit (SR7) (see Table 8) is set to a logic HIGH level (1), allowing the CSM to respond to the full command set again.

### **OPERATIONS**

Device operations are selected by entering a standard JEDEC 8-bit command code with conventional microprocessor timings into an on-chip CSM through I/Os DQ0–DQ7. The number of bus cycles required to activate a command is typically one or two. The first operation is always a WRITE. Control signals CE# and WE# must be at a logic LOW level (VIL), and OE# and

RP# must be at logic HIGH (VIH). The second operation, when needed, can be a WRITE or a READ depending upon the command. During a READ operation, control signals CE# and OE# must be at a logic LOW level (Vil), and WE# and RP# must be at logic HIGH (VIH).

Table 7 illustrates the bus operations for all the modes: write, read, reset, standby, and output disable.

When the device is powered up, internal reset circuitry initializes the chip to a read array mode of operation. Changing the mode of operation requires that a command code be entered into the CSM. An on-chip status register is available. The status register allows the monitoring of the progress of various operations that can take place on a memory. The status register is interrogated by entering a READ STATUS REGISTER command onto the CSM (cycle 1) and reading the register data on I/Os DQ0–DQ7 (cycle 2). Status register bits SR0–SR7 correspond to DQ0–DQ7 (see Table 8).

### **Command Definition**

Once a specific command code has been entered, the WSM executes an internal algorithm, generating the necessary timing signals to program, erase, and verify data. See Table 4 for the CSM command definitions and data for each of the bus cycles.

Table 3: Command State Machine Codes For Device Mode Selection

COMMAND DQ0-DQ7	CODE ON DEVICE MODE
40h/10h	Program setup/alternate program setup
20h	Block erase setup
50h	Clear status register
60h	Protection configuration setup
70h	Read status register
90h	Read protection configuration register
98h	Read query
B0h	Program/erase suspend
C0h	Protection register program/lock
D0h	Program/erase resume – erase confirm
FFh	Read array

### **STATUS REGISTER**

The status register allows the user to determine whether the state of a PROGRAM/ERASE operation is pending or complete. The status register is monitored by toggling OE# and CE# by reading the resulting status code on I/Os DQ0–DQ7. The high-order I/Os (DQ8–DQ15) are set to 00h internally, so only the low-order I/Os (DQ0–DQ7) need to be interpreted.

Register data is updated and latched on the falling edge of OE# or CE#, whichever occurs last. Latching the data prevents errors from occurring if the register input changes during a status register read.

The status register provides the internal state of the WSM to the external microprocessor. During periods when the WSM is active, the status register can be polled to determine the WSM status. Table 8 defines the status register bits.

After monitoring the status register during a PRO-GRAM/ERASE operation, the data appearing on DQ0–DQ7 remains as status register data until a new command is issued to the CSM. To return the device to other modes of operation, a new command must be issued to the CSM.

# COMMAND STATE MACHINE OPERATIONS

The CSM decodes instructions for read array, read protection configuration register, read query, read status register, clear status register, program, erase, erase suspend, erase resume, erase confirm, program setup, alternate program setup, program suspend, program resume, lock block, unlock block and lock down block, chip protection register program, and chip protection register lock. The 8-bit command code is input to the device on DQ0–DQ7 (see Table 3 for CSM codes and Table 4 for command definitions). During a PROGRAM or ERASE cycle, the CSM informs the WSM that a PROGRAM or ERASE cycle has been requested. During a PROGRAM cycle, the WSM controls the program sequences and the CSM responds to a PROGRAM SUS-PEND command only. During an ERASE cycle, the

CSM responds to an ERASE SUSPEND command only. When the WSM has completed its task, the WSM status bit (SR7) is set to a logic HIGH level and the CSM responds to the full command set. The CSM stays in the current command state until the microprocessor issues another command.

The WSM successfully initiates an ERASE or PRO-GRAM operation only when VPP is within its correct voltage range.

### **CLEAR STATUS REGISTER**

The internal circuitry can set, but not clear, the block lock status bit (SR1), the VPP status bit (SR3), the program status bit (SR4), and the erase status bit (SR5) of the status register. The CLEAR STATUS REGISTER command (50h) allows the external microprocessor to clear these status bits and synchronize to the internal operations. When the status bits are cleared, a READ ARRAY command (FFh) must be issued before data can be read from the memory array, or a READ STATUS REGISTER command (70h) must be issued to read status.

### **READ OPERATIONS**

The following READ operations are available: READ ARRAY, READ PROTECTION CONFIGURATION REGISTER, READ QUERY and READ STATUS REGISTER.

## **Read Array**

The array is read by entering the command code FFh on DQ0–DQ7. Control signals CE# and OE# must be at a logic LOW level (VIL), and WE# and RP# must be at logic HIGH level (VIH) to read data from the array. Data is available on DQ0–DQ15. Any valid address within any of the blocks selects that address and allows data to be read from that address. Upon initial power-up or device reset, the device defaults to the read array mode.

# Read Chip Protection Configuration Register

The chip identification mode outputs four types of information: the manufacturer/device identifier, the block locking status, the protection register content, and protection register lock. Two bus cycles are required for this operation: the chip identification data is read by entering the command code 90h on DQ0–

DQ7 and the identification code address on the address lines.

Control signals CE# and OE# must be at a logic LOW level (VIL), and WE# and RP# must be at a logic HIGH level (VIH) to read data from the protection configuration register. Data is available on DQ0–DQ15. To return to read array mode, write the read array command code FFh on DQ0–DQ7. See Table 10 for further details.

**Table 4: Command Definitions**

# **Table 5: Command Descriptions**

BUS						
CODE	DEVICE MODE	CYCLE	DESCRIPTION			
10h	Alt. Program Setup	First	Operates the same as a PROGRAM SETUP command.			
20h	Erase Setup	First	Prepares the CSM for an ERASE CONFIRM command. If the next command is not an ERASE CONFIRM command, the command will be ignored, and the device will go to read status mode and wait for another command.			
40h	Program Setup	First	A two-cycle command: The first cycle prepares for a PROGRAM operation, the second cycle latches addresses and data and initiates the WSM to execute the program algorithm. The Flash device outputs status register data on the falling edge of OE# or CE#, whichever occurs first.			
50h	Clear Status Register	First	The WSM can set the block lock status (SR1), VPP Status (SR3), program status (SR4), and erase status (SR5) bits in the status register to "1," but it cannot clear them to "0." Issuing this command clears those bits to "0."			
60h	Protection Configuration Setup	First	Prepares the CSM for changes to the block locking status. If the next command is not BLOCK UNLOCK, BLOCK LOCK, or BLOCK LOCK DOWN the CSM will set both the program and erase status register bits to indicommand sequence error.			
70h	Read Status Register	First	Places the device into read status register mode. Reading the device will output the contents of the status register for the addressed bank. The device will automatically enter this mode for the addressed bank after a PROGRAM or ERASE operation has been initiated.			
90h	Read Protection Configuration Register	First	Puts the device into the read protection configuration register mode so that reading the device will output the manufacturer/device codes, block lock status, protection register, or protection register lock.			
98h	Read Query	First	Puts the device into the read query mode so that reading the device will output common flash interface information.			
B0h	Program/Erase Suspend	First	Suspends the currently executing PROGRAM/ERASE operation. The status register will indicate when the operation has been successfully suspended by setting either the program suspend (SR2) or erase suspend (SR6) and the WSM status bit (SR7) to a "1" (ready). The WSM will continue to idle in the suspend state, regardless of the state of all input control pins except RP#, which will immediately shut down the WSM and the remainder of the chip if RP# is driven to VIL.			
C0h	Program Device Protection Register	First	Writes a specific code into the device protection register.			
	Lock Device Protection Register	First	Locks the device protection register; data can no longer be changed.			
D0h	Erase Confirm	Second	If the previous command was an ERASE SETUP command, then the CSM will close the address and data latches, and it will begin erasing the block indicated on the address pins. During programming/erase, the device will respond only to the READ STATUS REGISTER, PROGRAM/ERASE SUSPEND commands and will output status register data on the falling edge of OE# or CE#, whichever occurs last.			
	Program/Erase Resume	First	If a program or erase operation was previously suspended, this command will resume the operation.			
FFh	Read Array	First	During the read array mode, array data will be output on the data bus.			
01h	Lock Block	Second	If the previous command was PROTECTION CONFIGURATION SETUP, the CSM will latch the address and lock the block indicated on the address bus.			

# **Table 5: Command Descriptions (continued)**

CODE	DEVICE MODE	BUS CYCLE	DESCRIPTION
2Fh	Lock Down	Second	If the previous command was PROTECTION CONFIGURATION SETUP, the CSM will latch the address and lock down the block indicated on the address bus.
D0h	Unlock Block	Second	If the previous command was PROTECTION CONFIGURATION SETUP, the CSM will latch the address and unlock the block indicated on the address bus. If the block had been previously set to lock down, this operation will have no effect.
00h	Invalid/Reserved		Unassigned command that should not be used.

# **Read Query**

The read query mode outputs common flash interface (CFI) data when the device is read (see Table 12). Two bus cycles are required for this operation. It is possible to access the query by writing the read query command code 98h on DQ0–DQ7. Control signals CE# and OE# must be at a logic LOW level (VIL), and WE# and RP# must be at logic HIGH level (VIH) to read data from the query. The CFI data structure contains information such as block size, density, command set, and electrical specifications. To return to read array mode, write the read array command code FFh on DQ0–DQ7.

# **Read Status Register**

The status register is read by entering the command code 70h on DQ0–DQ7. Two bus cycles are required for this operation: one to enter the command code and a second to read the status register. In a READ cycle, the register data is updated on the falling edge of OE# or CE#, whichever occurs last.

### **PROGRAMMING OPERATIONS**

There are two CSM commands for programming: PROGRAM SETUP and ALTERNATE PROGRAM SETUP (see Table 3).

After the desired command code is entered (10h or 40h command code on DQ0-DQ7), the WSM takes over and correctly sequences the device to complete the PROGRAM operation. The WRITE operation may be monitored through the status register (see the Status Register section). During this time, the CSM will only respond to a PROGRAM SUSPEND command until the PROGRAM operation has been completed, after which time all commands to the CSM become valid again. The PROGRAM operation can be suspended by issuing a PROGRAM SUSPEND command (B0h). Once the WSM reaches the suspend state, it allows the CSM to respond only to READ ARRAY, READ STATUS REGISTER, READ PROTECTION CONFIGU-RATION, READ QUERY, and PROGRAM RESUME. During the PROGRAM SUSPEND operation, array data should be read from an address other than the one being programmed. To resume the PROGRAM operation, a PROGRAM RESUME command (D0h) must be issued to cause the CSM to clear the suspend state previously set (see Figure 4 for programming operation and Figure 5 for program suspend and program resume).

During programming, VPP must remain in the appropriate VPP voltage range as shown in the Recommended Operating Conditions table.

### **ERASE OPERATIONS**

An ERASE operation must be used to initialize all bits in an array block to "1". After BLOCK ERASE CONFIRM is issued, the CSM responds only to an ERASE SUSPEND command until the WSM completes its task.

Block erasure inside the memory array sets all bits within the address block to logic "1". Erase is accomplished only by blocks; data at single address locations within the array cannot be erased individually. The block to be erased is selected by using any valid address within that block. Block erasure is initiated by a command sequence to the CSM: BLOCK ERASE SETUP (20h) followed by BLOCK ERASE CONFIRM (D0h) (see Figure 6). A two-command erase sequence protects against accidental erasure of memory contents.

When the BLOCK ERASE CONFIRM command is complete, the WSM automatically executes a sequence of events to complete the block erasure. During this sequence, the block is programmed with logic "0", data is verified, all bits in the block are erased, and finally verification is performed to ensure that all bits are correctly erased. Monitoring the ERASE operation is possible through the status register (see the Status Register section).

During the execution of an ERASE operation the ERASE SUSPEND command (B0h) can be entered to direct the WSM to suspend the ERASE operation. Once the WSM has reached the suspend state, it allows the CSM to respond only to the READ ARRAY, READ STA-TUS REGISTER, READ QUERY, READ CHIP PROTEC-TION CONFIGURATION, **PROGRAM** SETUP, PROGRAM/ERASE RESUME and LOCK SETUP (see the Block Locking section). During the ERASE SUS-PEND operation, array data must be read from a block other than the one being erased. To resume the ERASE operation, an ERASE RESUME command (D0h) must be issued to cause the CSM to clear the suspend state previously set (see Figure 7). It is also possible that an ERASE can be suspended and a write to another block can be initiated. After the completion of a write, an erase can be resumed by writing an ERASE RESUME command.

### **BLOCK LOCKING**

The MT28F320A18 Flash memory provides a flexible locking scheme that allows each block to be individually locked or unlocked with no latency.

The device offers two-level protection for the blocks. The first level allows software-only control of block locking (for data that needs to be changed frequently), while the second level requires hardware interaction before locking can be changed (code that does not require frequent updates). Control pins WP#, DQ1, and DQ0 define the state of a block; for example, state [001] means WP# = 0, DQ1 = 0 and DQ0 = 1. Table 9 defines all of the possible locking states.

**Note:** All blocks are software-locked upon power-up sequence completion.

# **Locking operation**

The following summarizes the locking operation.

- All blocks are locked on power-up. They can then be unlocked or locked down with the UNLOCK and LOCK DOWN commands.
- 2. The LOCK DOWN command locks a block and prevents it from being unlocked when WP# = 0.
  - When WP# = 1, lock down is overridden. Commands can then unlock/lock locked down blocks.
  - When WP# returns to 0, locked down blocks return to lock down.
  - Lock down is cleared only when the device is reset or powered down.

# **Locked State**

After a power-up sequence completion, or after a reset sequence, all blocks are locked (states [001] or [101]). This means full protection from alteration. Any PROGRAM or ERASE operations attempted on a locked block will return an error on bit SR1 of the status register. The status of a locked block can be changed to unlocked or lock down using the appropriate software commands. Writing the lock command sequence, 60h followed by 01h, can lock an unlocked block.

### **Unlocked State**

Unlocked blocks (states [000], [100], [110]) can be programmed or erased. All unlocked blocks return to the locked state when the device is reset or powered down. An unlocked block can be locked or locked down using the appropriate software command sequence (see Table 4).

### **Locked Down State**

Blocks that are locked down (state [011]) are protected from PROGRAM and ERASE operations, but their protection status cannot be changed using software commands alone. A locked or unlocked block can be locked down by writing the lock down command sequence, 60h followed by 2Fh. Locked down blocks revert to the locked state when the device is reset or powered down.

The lock down function is dependent on the WP# input pin. When WP# = 0, blocks in lock down [011] are protected from program, erase and lock status changes. When WP# = 1, the lock down function is disabled ([111]) and locked down blocks can be individually unlocked by a software command to the [110] state, where they can be erased and programmed. These blocks can then be relocked [111] and unlocked [110] as desired as long as WP# remains HIGH. When WP# goes LOW, blocks that were previously locked down return to the locked down state [011] regardless of any changes made while WP# was HIGH. Device reset or power-down resets all locked blocks, including those in lock down, to locked state (see Table 9).

### **Reading a Block's Lock Status**

The lock status of every block can be read in the read device identification mode. To enter this mode, write 90h to the device. Subsequent READs at block address + 00002h will output the lock status of that block. The lowest two outputs, DQ0 and DQ1, represent the lock status. DQ0 indicates the block lock/unlock status and is set by the LOCK command and cleared by the UNLOCK command. It is also automatically set when entering lock down. DQ1 indicates lock down status and is set by the LOCK DOWN command. It can only be cleared by reset or power-down, not by software. Table 9 shows the locking state transition scheme.

# **Locking Operations during Erase Suspend**

Changes to block lock status can be performed during an ERASE SUSPEND by using the standard locking command sequences to unlock, lock, or lock down. This is useful in the case when another block needs to be updated while an ERASE operation is in progress.

To change block locking during an ERASE operation, first write the ERASE SUSPEND command (B0h), then check the status register until it indicates that the ERASE operation has been suspended. Next, write the desired lock command sequence to block lock, and the

lock status will be changed. After completing LOCK, READ or PROGRAM operations, resume the ERASE operation with the ERASE RESUME command (D0h).

If a block is locked or locked down during a suspend erase of the same block, the locking status bits will change immediately. But, when resumed, the erase operation will complete.

A locking operation cannot be performed during a PROGRAM SUSPEND.

# **Status Register Error checking**

Using nested locking or program command sequences during ERASE SUSPEND can introduce ambiguity into status register results.

Following protection configuration setup (60h), an invalid command will produce a lock command error (SR4 and SR5 will be set to "1") in the status register. If a lock command error occurs during an ERASE SUSPEND, SR4 and SR5 will be set to "1" and will remain at "1" after the ERASE SUSPEND is resumed. When the ERASE is complete, any possible error during the ERASE cannot be detected via the status register because of the previous locking command error.

A similar situation happens if an error occurs during a program operation error nested within an ERASE SUSPEND.

**Table 7: Bus Operations** 

MODE	RP#	CE#	OE#	WE#	ADDRESS	DQ0-DQ15
Read (array, status registers, device identification register, or query)	VIH	VIL	VIL	VIH	Х	Dout

STATUS BIT	STATUS DESISTED DIT	DESCRIPTION
#	STATUS REGISTER BIT	DESCRIPTION
SR7	WRITE STATE MACHINE STATUS (WSMS)	Check write state machine bit first to determine word program
	1 = Ready	or block erase completion, before checking program or erase
	0 = Busy	status bits.
SR6	ERASE SUSPEND STATUS (ESS)	When ERASE SUSPEND is issued, WSM halts execution and sets
	1 = BLOCK ERASE Suspended	both WSMS and ESS bits to "1." ESS bit remains set to "1" until
	0 = BLOCK ERASE in Progress/Completed	an ERASE RESUME command is issued.
SR5	ERASE STATUS (ES)	When this bit is set to "1," WSM has applied the maximum
	1 = Error in Block Erasure	number of erase pulses to the block and is still unable to verify
	0 = Successful BLOCK ERASE	successful block erasure.
SR4	PROGRAM STATUS (PS)	When this bit is set to "1," WSM has attempted but failed to
	1 = Error in PROGRAM	program a word.
	0 = Successful PROGRAM	
SR3	VPP STATUS (VPPS)	The VPP status bit does not provide continuous indication of the
	1 = VPP Low Detect, Operation Abort	VPP level. The WSM interrogates the VPP level only after the
	0 = VPP = OK	program or erase command sequences have been entered. The
		WSM informs the system if VPP < 0.9V. The VPP level is also
		checked before the PROGRAM/ERASE operation is verified by
		the WSM.
SR2	PROGRAM SUSPEND STATUS (PSS)	When PROGRAM SUSPEND is issued, WSM halts execution and
	1 = Program Suspended	sets both WSMS and PSS bits to "1." PSS bit remains set to "1"
	0 = Program in Progress/Completed	until a PROGRAM RESUME command is issued.
SR1	BLOCK LOCK STATUS (BLS)	If a PROGRAM or ERASE operation is attempted to one of the
	1 = PROGRAM/ERASE Attempted on a	locked blocks, this is set by the WSM. The operation specified is
	Locked Block; Operation Aborted	aborted and the device is returned to read status mode.
	0 = No operation to locked blocks	
SR0	RESERVED FOR FUTURE ENHANCEMENTS	This bit is reserved for future enhancements.

2. "XX" specifies the block address of lock configuration.

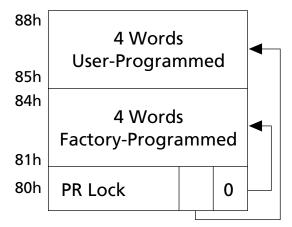

### **CHIP PROTECTION REGISTER**

A 128-bit protection register can be used to fulfill the security considerations in the system (preventing the device substitution).

The 128-bit security area is divided into two 64-bit segments. The first 64 bits are programmed at the manufacturing site with a unique 64-bit unchangeable number. The other segment is left blank for customers to program as desired. (See Figure 8).

Figure 8: Protection Register Memory Map

# **Reading the Chip Protection Register**

The chip protection register is read in the device identification mode, loading the 90h command to the bank containing address 00h. Once in this mode, READ cycles from addresses shown in Table 10 retrieve the specified information. To return to the read array mode, write the READ ARRAY command (FFh).

# Programming the Chip Protection Register

Executing the PROTECTION PROGRAM command enables the customer to program the user portion of the protection register. First, write the PROTECTION PROGRAM SETUP command, C0h; then write address and data to program.

Attempts should not be made to address PROTEC-TION PROGRAM commands outside the defined protection register address space. Attempting to program to a previously locked protection register segment will result in a status register error (program error bit SR4 and lock error bit SR1 = 1)

# **Locking the Chip Protection Register**

The customer-programmable segment of the protection register can be locked by programming bit 1 of the PR lock location to "0". Bit 0 of this location is programmed to a "0" at the Micron factory to protect the unique device number. Bit 1 is set using the PROTECTION PROGRAM command to program FFFDh to the PR lock location. After these bits have been programmed, no further changes can be made to the values stored in the protection register. PROTECTION PROGRAM commands to a locked section will result in a status register error program error bit SR4 and lock error bit SR1 will be set to 1. Protection register lockout is not reversible.

### **VPP/Vcc Program and Erase Voltages**

The MT28F320A18 Flash memory provides in-system programming and erase with VPP in the 0.9V-1.95V (VPP1) range. The 12V VPP (VPP2) mode programming is offered for compatibility with existing programming equipment. The fast programming algorithm is enabled at VPP = VPP2.

The device can withstand 100,000 WRITE/ERASE operations when VPP = VPP1 or 100 WRITE/ERASE operations and 10 cumulative hours when VPP = VPP2.

In addition to the flexible block locking, the VPP programming voltage can be held LOW for absolute hardware write protection of all blocks in the Flash device. When VPP is below VPPLK, any PROGRAM or ERASE operation will result in an error, prompting the corresponding status register bit (SR3) to be set.

During WRITE and ERASE operations, the WSM monitors the VPP voltage level. WRITE/ERASE operations are allowed only when VPP is within the range specified in TABLE 11.

When VCC is below VLKO or below VPPLK, any WRITE/ERASE operation will be disabled.

Table 11: VPP Range (V)

	MIN	МАХ
In-System (VPP1)	0.9	1.95
In-Factory (VPP2)	11.4	12.6

### **READ CYCLE**

Addresses can be accessed in a random order with an access time given by <sup>t</sup>AA = 70ns.

When CE# and OE# are LOW, the data is placed on the data bus and the processor can read the data.

### **STANDBY MODE**

ICC supply current is reduced by applying a logic HIGH level on CE# and RP# to enter the standby mode. In the standby mode, the outputs are placed in High-Z. Applying a CMOS logic HIGH level on CE# and RP# reduces the current to ICC2 (MAX). If the device is deselected during an ERASE operation or during programming, the device continues to draw current until the operation is complete.

# **AUTOMATIC POWER SAVE MODE (APS)**

Substantial power savings are realized during periods when the array is not being read and the device is in the active mode. During this time, the device switches to the automatic power saving mode. When the device switches to this mode, ICC is reduced to ICC2. The low level of power is maintained until another operation is initiated. In this mode, the I/O pins retain the data from the last memory address read until a new address is initiated. This mode is entered automatically if no address or control signal toggles.

### **POWER-UP SEQUENCE**

The following power-up sequence is recommended to properly initialize internal chip operations:

- At power-up, RST# should be kept at VIL for 2µs after VCC reaches VCC (MIN).
- VccQ should not come up before Vcc.
- VPP should be kept at VIL to maximize data integrity.

When the power-up sequence is completed, RST# should be brought to VIH. To ensure proper power-up, the rise time of RST# (10%-90%) should be  $< 10\mu$ S.

### **ABSOLUTE MAXIMUM RATINGS\***

 \*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

### RECOMMENDED OPERATING CONDITIONS

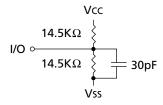

PARAMETER/CONDITION		SYMBOL	MIN	MAX	UNITS	NOTES
Operating temperature		<sup>t</sup> A	-40	+85	°C	
Vcc supply voltage		Vcc	1.65	1.95	V	
I/O supply voltage (Vcc = 1.65V–1.95V)		VccQ1	1.65	1.95	V	
Supply voltage, when used as logic control		VPP1	0.9	1.95	V	
VPP in-factory programming voltage		VPP2	11.4	12.6	V	
Block erase cycling VPP = VPP1		VPP1	100,000	_	Cycles	
	VPP = VPP2	VPP2	_	100	Cycles	1

**Notes: 1.** VPP = VPP2 is a maximum of 10 cumulative hours.
