## Advance Information

## PLL Tuning Circuit with 1.3 GHz Prescaler and D/A Converters for Automatic Tuner Alignment

The MC44864 is a tuning circuit for TV applications. This device contains a PLL section and a DAC section and is MCU controlled through an $I^{2} \mathrm{C}$ Bus.

The PLL section contains all the functions required to control the VCO of a TV tuner. The IC generates the tuning voltage and the additional control signals, such as band switching voltages.

The D/A section generates three additional varactor voltages to feed all of the varactors of the tuner with individually optimized control voltages (automatic tuner adjustment). The MC44864 is manufactured on a single silicon chip using Motorola's high density bipolar process, MOSIACTM (Motorola Oxide Self-Aligned Implanted Circuits).

- Complete Single Chip System for MPU Control
- Selectable $\div 8$ Prescaler Accepts Frequencies up to 1.3 GHz
- 15 Bit Programmable Divider Accepts Input Frequencies up to 165 MHz
- Programmable Reference Divider
- 3-State Phase/Frequency Comparator
- Operational Amplifier for Direct Varactor Control with Low Saturation Voltage
- Four Output Buffers ( 15 mA )
- Output Options for 62.5 kHz , Reference Frequency and the Programmable Divider
- The HF Input is Symmetrical
- Three 6 Bit DACs for Automatic Tuner Adjustment Allowing Use of Non-Matched Varactors
- Better Tuner Performances Through Optimum Filter Response
- ${ }^{2}$ C Bus Controlled
- Four Chip Addresses for the PLL Section
- Four Chip Addresses for the D/A Section
- ESD Protected to MIL-STD-883C, Method 3015.7
( $2,000 \mathrm{~V}, 1.5 \mathrm{k} \Omega, 150 \mathrm{pF}$ )

## MC44864

## FUNCTIONAL DESCRIPTION

A representative block diagram and a typical system application are shown in Figures 4 and 5. A discussion of the features and function of the internal blocks is given below.

## Automatic Tuner Alignment

The circuit generates the tuning voltage through the PLL. The output voltages of the D/A converters are equal to the tuning voltage plus a positive or negative offset of up to 31 steps. During the automatic alignment one first lets the PLL lock to the appropriate frequency and then searches for the
optimum value of the other varactor voltages. The digital word for each voltage value is stored in a nonvolatile memory (NVM). Hence, for each frequency point to be adjusted, three times 6 bits of information have to be stored (plus 2 bits for the DAC range).

The information stored in the NVM reflects the characteristic of the individual tuner. For this reason, the NVM is preferably situated inside the tuner and is also controlled by the $\mathrm{I}^{2} \mathrm{C}$ Bus.

Figure 4. Block Diagram

2. The crystal may be connected to Pin 20 with no connection to external Gnd.

## Chip Addresses

The chip address is programmable by Pin CA.
The PLL addresses C0, C2, C4, C6 are officially allocated to PLL-IC's.

The addresses C8, CA, CC, CE are not officially allocated. Care has to be taken in the application that no conflict occurs with other devices on the same $\mathrm{I}^{2} \mathrm{C}$ Bus when using the addresses C 8 to CE .

## PLL SECTION

## Data Format and Bus Receiver

The circuit receives the information for tuning and control via ${ }^{2} \mathrm{C}$ Bus. The incoming information is treated in the bus receiver. The definition of the permissible bus protocol is shown in the four examples below:

| Ex. 1 | STA | CA1 | CO | BA | STO |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Ex.2 | STA | CA1 | FM | FL | STO |  |  |
| Ex.3 | STA | CA1 | CO | BA | FM | FL | STO |
| Ex. 4 | STA | CA1 | FM | FL | CO | BA | STO |

Ex. 4 STA CA1
STO = Stop Condition
CA1 = Chip Address Byte of the PLL Section
CO = Data Byte for Control Information
$B A=$ Band Information
FM = Data Byte for Frequency Information (MSB's)
FL = Data Byte for Frequency Information (LSB's)
Figure 6 shows the five bytes of information that are needed for circuit operation: there is a chip address, two bytes of control and band information and two bytes of frequency information.

After the chip address, two or four data bytes may be received: if three data bytes are received, the third data byte is ignored. If five or more data bytes are received, the fifth and following data bytes are ignored and the last acknowledge pulse is sent at the end of the fourth data byte.

The first and the third data bytes contain a function bit F . If the function bit $\mathrm{F}=0$, frequency information is acknowledged and if $F=1$, control/band information is acknowledged.

If the address is correct (signal AD1) the information is loaded into latches.

A function bit in the first and third data byte is used to pass this data either into the latches of the programmable divider (signal DTF) or into the latches for band and control information (signal DTB). The data transfer to the latches (signals DTF and DTB) is initiated after the 2nd and 4th data bytes.

A second string of latches is used for the data transfer into the programmable divider to inhibit the transfer during the preset operation (signal TDI, signal AVA is an internal "address valid" command).

The switching levels of clock and data (Pins 18 and 19) are $0.5 \times \mathrm{V}_{\mathrm{CC}} 1$.

The control and band information bits have the following functions.

## Bits $\mathbf{R}_{\mathbf{0}}, \mathbf{R}_{\mathbf{1}}$ : Controls Reference Divider Division Ratio

| $\mathbf{R}_{\mathbf{0}}$ | $\mathbf{R}_{\mathbf{1}}$ | Division Ratio |
| :---: | :---: | :---: |
| 0 | 0 | 2048 |
| 1 | 0 | 1024 |
| 0 | 1 | 512 |
| 1 | 1 | 256 |

Bits $\mathbf{R}_{\mathbf{2}}, \mathbf{R}_{3}$ : Switches Internal Signals to the Buffer Outputs

| $\mathbf{R}_{\mathbf{2}}$ | $\mathbf{R}_{\mathbf{3}}$ | Pin $\mathbf{1 6}$ | Pin $\mathbf{1 7}$ |
| :---: | :---: | :---: | :---: |
| 0 | 0 | - | - |
| 0 | 1 | 62.5 kHz | - |
| 1 | 0 | $\mathrm{~F}_{\text {ref }}$ | $\mathrm{F}_{\mathrm{BY2}}$ |
| 1 | 1 | - | - |

Bit $\mathrm{B}_{5}$ has to be "one" when Pin 16 is used to output 62.5 kHz . Bits $\mathrm{B}_{5}$ and $\mathrm{B}_{7}$ have to be "one" to output $\mathrm{F}_{\text {ref }}$ and $\mathrm{F}_{\mathrm{BY}} 2$. $\mathrm{F}_{\mathrm{BY} 2}$ is the programmable divider output frequency divided by two.
Bits $\mathbf{R}_{\mathbf{2}}, \mathbf{R}_{\mathbf{6}}$, T: Controls the Phase Comparator Output Stage

| $\mathbf{R}_{\mathbf{2}}$ | $\mathbf{R}_{\mathbf{6}}$ | $\mathbf{T}$ | Output State |
| :---: | :---: | :---: | :--- |
| 0 | 0 | 0 | Normal Operation |
| 0 | 0 | 1 | "Off" (High Impedance) |
| 0 | 1 | 0 | High |
| 0 | 1 | 1 | Low |
| 1 | 0 | 0 | Normal Operation |
| 1 | 0 | 1 | "Off" |
| 1 | 1 | 0 | Normal Operation |
| 1 | 1 | 1 | "Off" |

## The Band Buffers

The band buffers are open collector transistors and are active "low" at $\mathrm{Bn}=1$. They are designed for 15 mA with typical on-voltage of 1.8 V . These buffers are designed to withstand relative high output voltage in the off-state ( 15 V ).
$B_{5}$ and $B_{7}$ buffers (Pins 16 and 17) may also be used to output internal IC signals (reference frequency and programmable divider output frequency divided by 2 ) for test purposes.

Buffer $\mathrm{B}_{5}$ may also be used to output a 62.5 kHz frequency from an intermediate stage of the reference divider. The bits $B_{5}$ and $B_{7}$ have to be "one" if the buffers are used for these additional functions.

## The Programmable Divider

The programmable divider is a presettable down counter. When it has counted to zero it takes its required division ratio out of the latches B. Latches B are loaded from latches A by means of signal TDI which is synchronous to the programmable divider output signal.

Since latches A receive the data asynchronously with the programmable divider, this double latch scheme is needed to assure correct data transfer to the counter.

The division ratio definition is given by:
$\mathrm{N}=16384 \times \mathrm{N}_{14}+8192 \times \mathrm{N}_{13}+\ldots+4 \times \mathrm{N}_{2}+2 \times \mathrm{N}_{1}+\mathrm{N}_{0}$
Maximum Ratio 32767
Minimum Ratio 256
where $\mathrm{N}_{0} \ldots \mathrm{~N}_{14}$ are the different bits for frequency information.

The counter reloads correctly as long as its output frequency does not exceed 1.0 MHz .

Division ratios of < 256 are not allowed. At power-up the counter bit N 8 is preset to " 1 ". All other bits are undetermined. In this way, the counter always starts with a division ratio of 256 or higher.

The data transfer between latches $A$ and $B$ (signal TDI) is also initiated by any start condition on the bus.

At power-on the whole bus receiver is reset and the programmable divider is set to a counting ratio of $\mathrm{N}=256$ or higher.

## The Prescaler

The prescaler has a preamplifier and may be bypassed (Bit P). The signal then passes through preamplifier 2.

The table on the following page shows the frequency ranges which may be synthesized with and without prescaler.

## The Phase Comparator

The phase comparator is phase and frequency sensitive and has very low output leakage current in the high impedance state.

## The Operational Amplifier

The operational amplifier for the tuning voltage is designed for low noise, low input bias current and high power supply rejection. The positive input is biased internally. The operational amplifier needs 30 V supply ( $\mathrm{V}_{\mathrm{CC} 2}$ ) as minimum voltage for a guaranteed maximum tuning voltage of 28.5 V .

Figure 4 shows the usual filter arrangement. The component values depend very much on the application (tuner characteristic, reference frequency, etc.).

As a starting point for optimization, the component values in Figure 4 may be used for 7.8125 kHz reference frequency in a multiband TV tuner.

## The Oscillator

The oscillator uses a 4.0 MHz crystal tied to ground in series with a capacitor. The crystal operates in the series resonance mode.

The crystal is driven through a $1.6 \mathrm{k} \Omega$ resistor on chip.
The voltage at Pin 16 "crystal", has low amplitude and low harmonic distortion.

The negative resistance of the oscillator at Pin 1 (XTAL) is about $3.0 \mathrm{k} \Omega$.

| 1 | 1 | 256 | 15625.0 | 125.0 | 1300(2) | 15.625 | 165(3) |

NOTES: 1. With 4.0 MHz Crystal
2. Limit of Prescaler
3. Limit of Programmable Divider

For satellite tuner applications the circuit may be used with an external /4 prescaler and a reference divider ration of $1024\left(R_{0}=1, R_{1}=0\right)$. In this way, frequencies up to 4.0 GHz can be synthesized with 125 kHz resolution ( 4.0 MHz crystal).

The same result can be achieved with an external / 32 prescaler when the internal prescaler is bypassed $(P=1$ ).

## The Reference Divider

The reference divider of the MC44864 is programmable (Bits $R_{0}$ and $R_{1}$ ) for ratios of 2048, 1024, 512 and 256. This feature makes the circuit versatile.

## D/A SECTION

## Basic Function

The D/A section has four separate chip addresses from the PLL section. Three D-to-A converters that have a resolution of 6 bits ( 5 bits plus sign) are on chip. The analog output voltages are dc. The converters are buffered to the analog outputs DA1, DA2 and DA3 by operational amplifiers with an output voltage range that is equal to the tuning voltage range (about 0 to 30 V ). The operational amplifiers are arranged such that a positive or negative offset can be generated from the tuning voltage.

## Data Format and Bus Protocols

The D-to-A information consists of the D/A chip address (CA2) and four data bytes. The first two bits of the data bytes are used as the function address. Thus the bytes $\mathrm{C}_{1}, \mathrm{C}_{2}$ and

C3 contain the address for the individual converter and the 6 bits to be converted. Bit $D_{5}$ is the sign (log "1" for positive offset, log " 0 " for negative offset) and the bits $\mathrm{D}_{0}$ to $\mathrm{D}_{4}$ determine the number of steps to be made as an offset from the tuning voltage. The bits $S_{0}$ and $S_{1}$ in the data byte RA define the step size ( $\mathrm{V}_{\text {step }}$ ) and the range of the converters (see Figures 8 and 9 ). The range is the same for all converters.

After the chip address (CA2) is acknowledged, up to four data bytes may be received by the IC. If more than four bytes are received, the fifth and following bytes are ignored and the last acknowledge pulse is sent after the fourth data byte. The data transfer to the converters (signal DTC) is initiated each time a complete data byte is received.
The following shows some examples of the permissible bus protocols of the D-to-A section. The data bytes may be sent to the IC in random order with up to four in one sequence. The same converter may be loaded up to four times as shown in example 6. Below are 6 examples of permissible bus protocols.

| Ex. 1 | STA | CA2 | C1 | STO |  |  |  |

| 0 | 0 | 225 mV | 6.25 V |
| 1 | 0 | 125 mV | 3.40 V |
| 0 | 1 | 70 mV | 1.90 V |
| 1 | 1 | 40 mV | 1.05 V |

## The D/A Converters

The D/A converters convert 5 bit into analog current of which the polarity is switched by the sixth bit. The reference voltage of the converters is programmed by two bits ( $\mathrm{S}_{0}, \mathrm{~S}_{1}$ of the RA-byte) to determine the scaling factor. The analog
currents are then converted into voltages and added to their respective operational amplifier nominal bias. The resulting voltages at Pins 6, 7 and 8 are the tuning voltages ( $V_{T U N}$, see Figure 4) at Pin 5 plus any offset provided by information in the D/A converters.
If the data bits $D_{0}$ to $D_{4}$ are all " 0 ", the three $D / A$ output voltages on Pins 6, 7 and 8 are equal to the tuning voltage (Pin 5) within the DAC offset voltages.
The four amplifiers have the same output characteristics with the maximum output voltage being 1.5 V lower than $\mathrm{V}_{\mathrm{CC}}$ in the worst case. The four analog outputs are short-circuit protected. At power-up, the D/A outputs are undetermined.
The D/A converters are guaranteed to be monotonic with a voltage step variation of $\pm 0.5$ LSB

The D/A converters work correctly as long as the PLL loop is active. $\mathrm{V}_{\text {TUN }}$ is then between 0.3 V and $\mathrm{V}_{\mathrm{CC}} 2-1.5 \mathrm{~V}$. If the oop saturates, the DACs do not work.
The DAC-OFFSET is defined as the difference between the DAC output voltage (with bits $\mathrm{D}_{0}$ to $\mathrm{D}_{4}=0$ ) and the tuning voltage (PLL active). The DAC operation is guaranteed from 0.3 V to $\mathrm{V}_{\mathrm{C} C 2}-1.5 \mathrm{~V}$. On typical samples, the DACs will operate down to 0.2 V .

1 DIMENSIONING AND TOLERANCING PER ANSI Y14.5M, 1982.
2 CONTROLLING DIMENSION: MILLIMETER.
3 DIMENSIONS D AND E DO NOT INCLUDE MOLD
FLASH OR PROTRUSIONS AND ARE MEASURED AT THE PARTING LINE. MOLD FLASH OR PROTRUSIONS SHALL NOT EXCEED 0.15 (0.006) PER SIDE.
4 TERMINAL NUMBERS ARE SHOWN FOR REFERENCE ONLY.
5 THE LEAD WIDTH DIMENSION (b) DOES NOT INCLUDE DAMBAR PROTRUSION. ALLOWABLE DAMBAR PROTRUSION SHALL BE 0.08 (0.003) TOTAL IN EXCESS OF THE LEAD WIDTH DIMENSION AT MAXIMUM MATERIAL CONDITION. DAMBAR CANNOT BE LOCATED ON THE LOWER RADIUS OR THE FOOT. MINIMUM SPACE BETWEEN PROTRUSIONS AND ADJACENT LEAD TO BE 0.46 ( 0.018 ).
