

# DS90CR287/DS90CR288 +3.3V Rising Edge Data Strobe LVDS 28-Bit Channel Link-75 MHz

#### **General Description**

**Block Diagrams** 

The DS90CR287 transmitter converts 28 bits of CMOS/TTL data into four LVDS (Low Voltage Differential Signaling) data streams. A phase-locked transmit clock is transmitted in parallel with the data streams over a fifth LVDS link. Every cycle of the transmit clock 28 bits of input data are sampled and transmitted. The DS90CR288 receiver converts the four LVDS data streams back into 28 bits of CMOS/TTL data. At a transmit clock frequency of 75 MHz, 28 bits of TTL data are transmitted at a rate of 525 Mbps per LVDS data channel. Using a 75 MHz clock, the data throughput is 2.10 Gbit/s (262.5 Mbytes/sec).

This chipset is an ideal means to solve EMI and cable size problems associated with wide, high speed TTL interfaces.

### Features

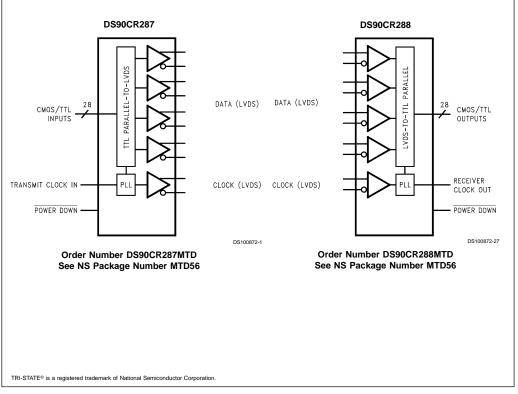

- 20 to 75 MHz shift clock support
- 50% duty cycle on receiver output clock
- Best-in-Class Set & Hold Times on TxINPUTs and **RxOUTPUTs**

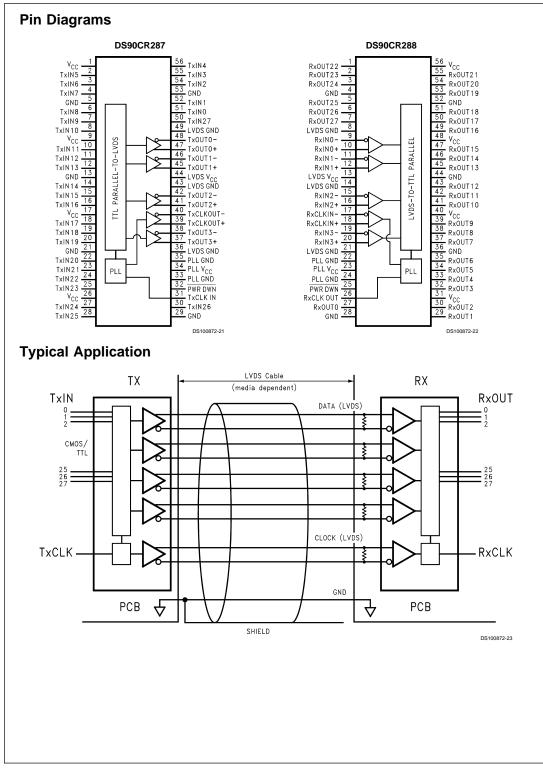

DS90CR287/DS90CR288 +3.3V Rising Edge

Data Strobe LVDS 28-Bit Channel Link-75 MHz

March 1999

- Low power consumption
- Tx + Rx Power-down mode <400µW (max)
- ±1V common mode range (around +1.2V)
- Narrow bus reduces cable size and cost
- Up to 2.10 Gbps throughput
- Up to 262.5 Megabytes/sec bandwidth
- 345 mV (typ) swing LVDS devices for low EMI
- PLL requires no external components
- Rising edge data strobe
- Compatible with TIA/EIA-644 LVDS standard
- Low profile 56-lead TSSOP package

Note 1: "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. They are not meant to imply that the device should be operated at these limits. The tables of "Electrical Characteristics" specify conditions for device operation.

Note 2: Typical values are given for V\_{CC} = 3.3V and T\_A = +25  $^\circ\text{C}.$ 

Note 3: Current into device pins is defined as positive. Current out of device pins is defined as negative. Voltages are referenced to ground unless otherwise specified (except V<sub>OD</sub> and  $\Delta$ V<sub>OD</sub>).

Note 4: V<sub>OS</sub> previously referred as V<sub>CM</sub>.

. .

Note 5: Receiver Skew Margin is defined as the valid data sampling region at the receiver inputs. This margin takes into account the transmitter pulse positions (min and max) and the receiver input setup and hold time (internal data sampling window-RSPOS). This margin allows LVDS interconnect skew, inter-symbol interference (both dependent on type/length of cable), and source clock (less than 250 ps).

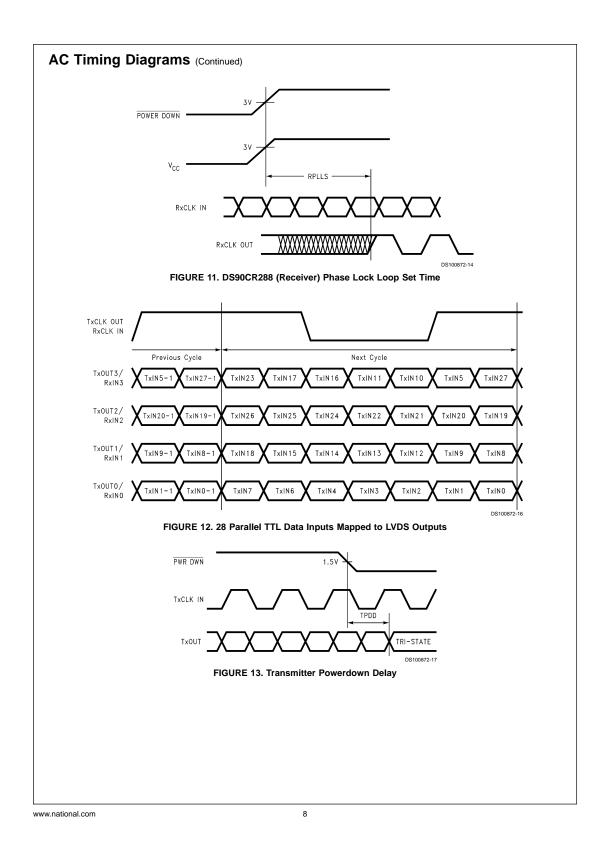

Note 6: Total latency for the channel link chipset is a function of clock period and gate delays through the transmitter (TCCD) and receiver (RCCD). The total latency for the 217/287 transmitter and 218/288 receiver is: (T + TCCD) + (2\*T + RCCD), where T = Clock period.

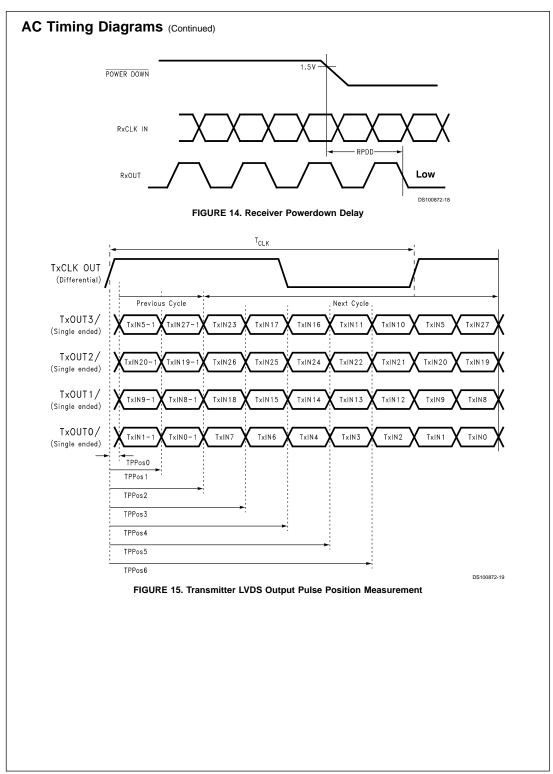

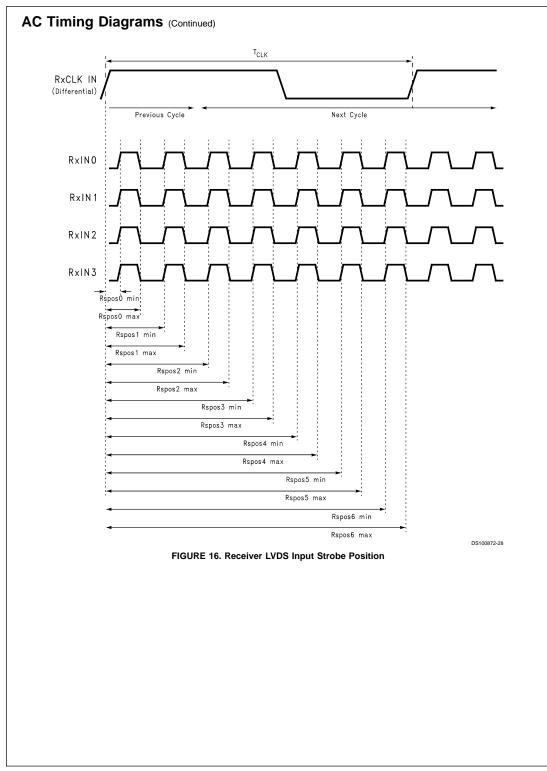

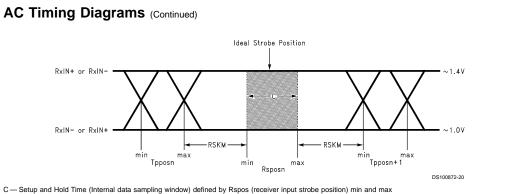

7

Tppos — Transmitter output pulse position (min and max) RSKM ≥ Cable Skew (type, length) + Source Clock Jitter (cycle to cycle)(Note 10) + ISI (Inter-symbol interference)(Note 11) Cable Skew - typically 10 ps-40 ps per foot, media dependent

Note 10: Cycle-to-cycle jitter is less than 250ps at 75MHz.

Note 11: ISI is dependent on interconnect length; may be zero

#### FIGURE 17. Receiver LVDS Input Skew Margin

#### **Applications Information**

.

The DS90CR287 and DS90CR288 are backward compatible with the existing 5V Channel Link transmitter/receiver pair (DS90CR283, DS90CR284). To upgrade from a 5V to a 3.3V system the following must be addressed:

1. Change 5V power supply to 3.3V. Provide this supply to the V\_{CC}, LVDS V\_{CC} and PLL V\_{CC}.

- 2. Transmitter input and control inputs except 3.3V TTL/ CMOS levels. They are not 5V tolerant.
- 3. The receiver powerdown feature when enabled will lock receiver output to a logic low. However, the 5V/66 MHz receiver maintain the outputs in the previous state when powerdown occurred.

# DS90CR287 Pin Description—Channel Link Transmitter

Pin Name	I/O	No.	Description
TxIN	1	28	TTL level input.
TxOUT+	0	4	Positive LVDS differential data output.
TxOUT-	0	4	Negative LVDS differential data output.
TxCLK IN	1	1	TTL level clock input. The rising edge acts as data strobe. Pin name TxCLK IN.
TxCLK OUT+	0	1	Positive LVDS differential clock output.
TxCLK OUT-	0	1	Negative LVDS differential clock output.
PWR DWN	I	1	TTL level input. Assertion (low input) TRI-STATES the outputs, ensuring low current at power down.
V <sub>cc</sub>	I	4	Power supply pins for TTL inputs.
GND	1	5	Ground pins for TTL inputs.
PLL V <sub>CC</sub>	1	1	Power supply pin for PLL.
PLL GND	1	2	Ground pins for PLL.
LVDS V <sub>CC</sub>	1	1	Power supply pin for LVDS outputs.
LVDS GND	1	3	Ground pins for LVDS outputs.

# DS90CR288 Pin Description—Channel Link Receiver

Pin Name	I/O	No.	Description
RxIN+	1	4	Positive LVDS differential data inputs. (Note 12)
RxIN-	1	4	Negative LVDS differential data inputs. (Note 12)
RxOUT	0	28	TTL level data outputs.
RxCLK IN+	1	1	Positive LVDS differential clock input.
RxCLK IN-	1	1	Negative LVDS differential clock input.
RxCLK OUT	0	1	TTL level clock output. The rising edge acts as data strobe. Pin name RxCLK OUT.

#### Applications Information (Continued)

#### DS90CR288 Pin Description—Channel Link Receiver (Continued)

Pin Name	I/O	No.	Description
PWR DWN	I	1	TTL level input.When asserted (low input) the receiver outputs are low.
V <sub>cc</sub>	I	4	Power supply pins for TTL outputs.
GND	I	5	Ground pins for TTL outputs.
PLL V <sub>CC</sub>	I	1	Power supply for PLL.
PLL GND	I	2	Ground pin for PLL.
LVDS V <sub>CC</sub>	Ι	1	Power supply pin for LVDS inputs.
LVDS GND	I	3	Ground pins for LVDS inputs.

Note 12: These receivers have input failsafe bias circuitry to guarantee a stable receiver output for floating or terminated receiver inputs. Under these conditions receiver inputs will be in a HIGH state. If a clock signal is present, outputs will all be HIGH; if the clock input is also floating/terminated outputs will remain in the last valid state. A floating/terminated clock input will a stable valid state. A floating/terminated clock input will a stable valid state. A floating/terminated clock input will remain in the last valid state. A floating/terminated clock input will remain in the last valid state. A floating/terminated clock input will remain in the last valid state. A floating/terminated clock input will remain in the last valid state. A floating/terminated clock input will remain in the last valid state. The Channel Link devices are intended to be used in a wide variety of data transmission applications. Depending upon the application the interconnecting media may vary. For example, for lower data rate (clock rate) and shorter cable lengths (< 2m), the media electrical performance is less critical. For higher speed/long distance applications the media's performance becomes more critical. Certain cable constructions provide tighter skew (matched electrical length between the conductors and pairs). Twin-coax for example, has been demonstrated at distances as great as 5 meters and with the maximum data transfer of 2.10 Gbit/s. Additional applications information can be found in the following National Interface Application Notes:

AN-916	Cable Information

**CABLES:** A cable interface between the transmitter and receiver needs to support the differential LVDS pairs. The 21bit CHANNEL LINK chipset (DS90CR217/218) requires four pairs of signal wires and the 28-bit CHANNEL LINK chipset (DS90CR287/288) requires five pairs of signal wires. The ideal cable/connector interface would have a constant  $100\Omega$ differential impedance throughout the path. It is also recommended that cable skew remain below 130ps (75 MHz clock rate) to maintain a sufficient data sampling window at the receiver.

In addition to the four or five cable pairs that carry data and clock, it is recommended to provide at least one additional conductor (or pair) which connects ground between the transmitter and receiver. This low impedance ground provides a common mode return path for the two devices. Some of the more commonly used cable types for point-to-point applications include flat ribbon, flex, twisted pair and Twin-Coax. All are available in a variety of configurations and options. Flat ribbon cable, flex and twisted pair generally perform well in short point-to-point applications. When using ribbon cable, it is recommended to place a ground line between each differential pair to act as a barrier to noise coupling between adjacent pairs. For Twin-Coax cable applications, it is recommended to reach cable pair. All extenses the action of the sheet o

tended point-to-point applications should also employ an overall shield surrounding all cable pairs regardless of the cable type. This overall shield results in improved transmission parameters such as faster attainable speeds, longer distances between transmitter and receiver and reduced problems associated with EMS or EMI.

The high-speed transport of LVDS signals has been demonstrated on several types of cables with excellent results. However, the best overall performance has been seen when using Twin-Coax cable. Twin-Coax has very low cable skew and EMI due to its construction and double shielding. All of the design considerations discussed here and listed in the supplemental application notes provide the subsystem communications designer with many useful guidelines. It is recommended that the designer assess the tradeoffs of each application thoroughly to arrive at a reliable and economical cable solution.

BOARD LAYOUT: To obtain the maximum benefit from the noise and EMI reductions of LVDS, attention should be paid to the layout of differential lines. Lines of a differential pair should always be adjacent to eliminate noise interference from other signals and take full advantage of the noise canceling of the differential signals. The board designer should also try to maintain equal length on signal traces for a given differential pair. As with any high speed design, the impedance discontinuities should be limited (reduce the numbers of vias and no 90 degree angles on traces). Any discontinuities which do occur on one signal line should be mirrored in the other line of the differential pair. Care should be taken to ensure that the differential trace impedance match the differential impedance of the selected physical media (this impedance should also match the value of the termination resistor that is connected across the differential pair at the receiver's input). Finally, the location of the CHANNEL LINK TxOUT/ RxIN pins should be as close as possible to the board edge so as to eliminate excessive pcb runs. All of these considerations will limit reflections and crosstalk which adversely effect high frequency performance and EMI.

**UNUSED INPUTS:** All unused inputs at the TxIN inputs of the transmitter must be tied to ground. All unused outputs at the RxOUT outputs of the receiver must then be left floating. **TERMINATION:** Use of current mode drivers requires a terminating resistor across the receiver inputs. The CHANNEL LINK chipset will normally require a single  $100\Omega$  resistor between the true and complement lines on each differential pair of the receiver input. The actual value of the termination resistor should be selected to match the differential mode

#### Applications Information (Continued)

characteristic impedance  $(90\Omega \text{ to } 120\Omega \text{ typical})$  of the cable. *Figure 18* shows an example. No additional pull-up or pulldown resistors are necessary as with some other differential technologies such as PECL. Surface mount resistors are recommended to avoid the additional inductance that accompanies leaded resistors. These resistors should be placed as close as possible to the receiver input pins to reduce stubs and effectively terminate the differential lines. **DECOUPLING CAPACITORS:** Bypassing capacitors are needed to reduce the impact of switching noise which could limit performance. For a conservative approach three parallel-connected decoupling capacitors (Multi-Layered Ceramic type in surface mount form factor) between each V<sub>CC</sub> and the ground plane(s) are recommended. The three capacitor values are 0.1 µF, 0.01 µF and 0.001 µF. An example is shown in *Figure 19*. The designer should employ wide traces for power and ground and ensure each capacitor has its own via to the ground plane. If board space is limiting the number of bypass capacitors, the PLL V<sub>CC</sub> should receive the most filtering/bypassing. Next would be the LVDS V<sub>CC</sub> pins and finally the logic V<sub>CC</sub> pins.

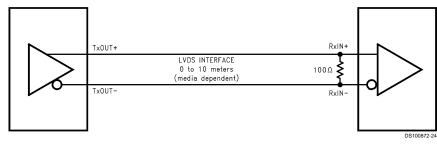

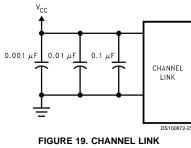

FIGURE 18. LVDS Serialized Link Termination

Decoupling Configuration

**CLOCK JITTER:** The CHANNEL LINK devices employ a PLL to generate and recover the clock transmitted across the LVDS interface. The width of each bit in the serialized LVDS data stream is one-seventh the clock period. For example, a 75 MHz clock has a period of 13.33 ns which results in a data bit width of 1.90 ns. Differential skew ( $\Delta t$  within one differential pair), interconnect skew ( $\Delta t$  of one differential pair to another) and clock jitter will all reduce the available window for sampling the LVDS serial data streams. Care must be taken to ensure that the clock input to the transmitter be a clean low noise signal. Individual bypassing of each V<sub>CC</sub> to ground will minimize the noise passed on to the PLL, thus

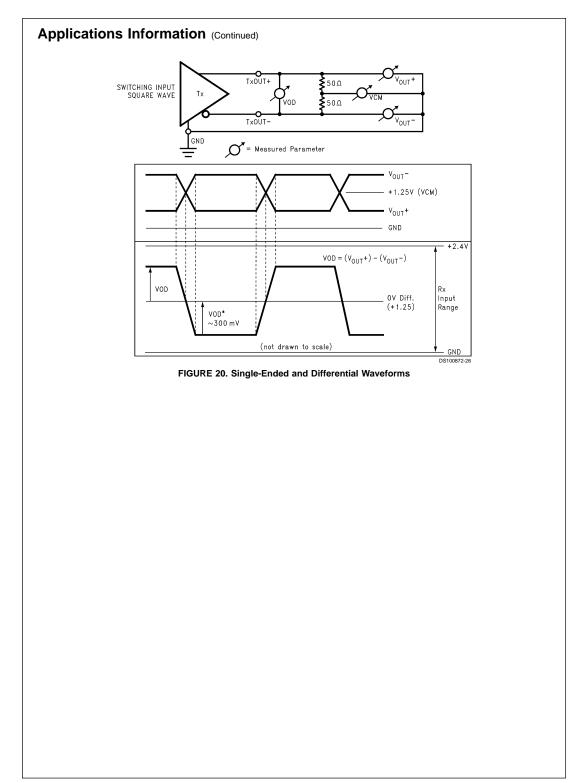

creating a low jitter LVDS clock. These measures provide more margin for channel-to-channel skew and interconnect skew as a part of the overall jitter/skew budget.

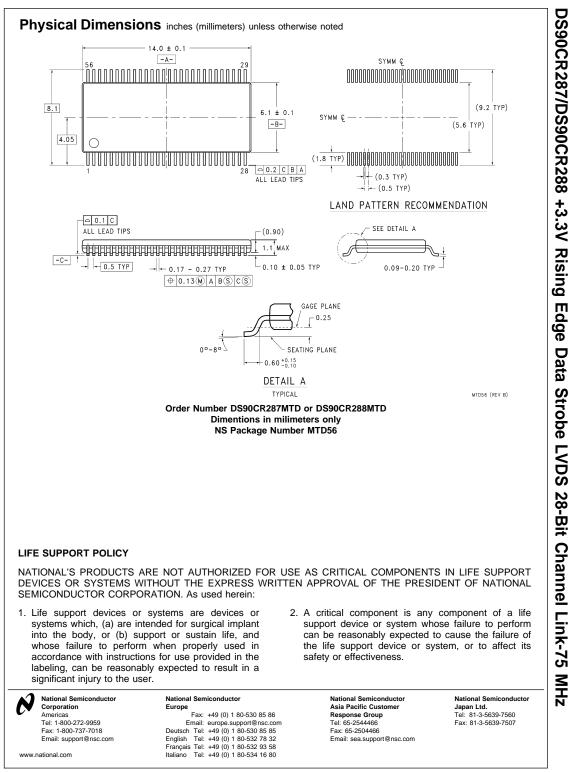

**COMMON MODE vs. DIFFERENTIAL MODE NOISE MAR-GIN:** The typical signal swing for LVDS is 300 mV centered at +1.2V. The CHANNEL LINK receiver supports a 100 mV threshold therefore providing approximately 200 mV of differential noise margin. Common mode protection is of more importance to the system's operation due to the differential data transmission. LVDS supports an input voltage range of Ground to +2.4V. This allows for a ±1.0V shifting of the center point due to ground potential differences and common mode noise.

**POWER SEQUENCING AND POWERDOWN MODE:** Outputs of the CNANNEL LINK transmitter remain in TRI-STATE® until the power supply reaches 2V. Clock and data outputs will begin to toggle 10 ms after  $V_{\rm CC}$  has reached 3V and the Powerdown pin is above 1.5V. Either device may be placed into a powerdown mode at any time by asserting the Powerdown pin (active low). Total power dissipation for each device will decrease to 5  $\mu$ W (typical).

The CHANNEL LINK chipset is designed to protect itself from accidental loss of power to either the transmitter or receiver. If power to the transmit board is lost, the receiver clocks (input and output) stop. The data outputs (RxOUT) retain the states they were in when the clocks stopped. When the receiver board loses power, the receiver inputs are shorted to V  $_{\rm CC}$  through an internal diode. Current is limited (5 mA per input) by the fixed current mode drivers, thus avoiding the potential for latchup when powering the device.
