

OKI Semiconductor

MSM541222A

REVISION-3 1999.6.10

262,214-Word x 12-Bit Field Memory

DESCRIPTION

The OKI MSM541222A is a high performance 3-Mbit, 256K X 12-bit, Field Memory. It is especially designed for high-speed serial access applications such as HDTVs, conventional NTSC TVs, VTRs, digital movies and Multi-media systems. MSM541222A is a FRAM for wide or low end use in general commodity TVs and VTRs exclusively. MSM541222A is not designed for high end use in medical systems, professional graphics systems which require long term picture storage, data storage systems and others. Two or more MSM541222As can be cascaded directly without any delay devices between them. (Cascading provides larger storage depth or a longer delay).

Each of the 12-bit planes has separate serial write and read ports. These employ independent control clocks to support asynchronous read and write operations. Different clock rates are also supported, which allow alternate data rates between write and read data streams.

The MSM541222A provides high speed FIFO, First-In First-Out, operation without external refreshing: MSM541222A refreshes its DRAM storage cells automatically, so that it appears fully static to the users.

Moreover, fully static type memory cells and decoders for serial access enable the refresh free serial access operation, so that serial read and/or write control clock can be halted high or low for any duration as long as the power is on. Internal conflicts of memory access and refreshing operations are prevented by special arbitration logic.

The MSM541222A's function is simple, and similar to a digital delay device whose delay-bit-length is easily set by reset timing. The delay length, and the number of read delay clocks between write and read, is determined by externally controlled write and read reset timings.

Additional SRAM serial registers, or line buffers for the initial access of 256 X 12-bit enable high speed first-bit-access with no clock delay just after the write or read reset timings.

Additionally, the MSM541222A has a write mask function or input enable function (IE), and read-data skipping function or output enable function (OE). The differences between write enable (WE) and input enable (IE), and between read enable (RE) and output enable (OE) are that WE and RE can stop serial write/read address increments, but IE and OE cannot stop the increment, when write/read clocking is continuously applied to MSM541222A. The input enable (IE) function allows the user to write into selected locations of the memory only, leaving the rest of the memory contents unchanged. This facilitates data processing to display a "picture in picture" on a TV screen.

The MSM541222A is similar in operation and functionality to OKI 1-Mbit Field Memory MSM514222C and 2-Mbit Field Memory MSM518222A. Three MSM514222Cs or one MSM514222C plus one MSM518222A can be replaced simply by one MSM541222A.

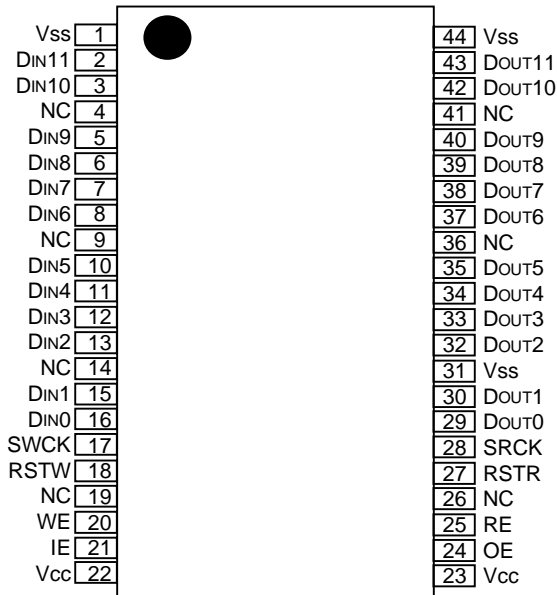

FEATURES

- Single power supply : 5 V \pm 10%
 - 512 Rows X 512 Columns X 12 bits
 - Fast FIFO (First-In First-Out) operation
 - High speed asynchronous serial access
 - Read/write cycle time 25 ns/30 ns
 - Access time 23 ns/25 ns
 - Direct cascading capability
 - Write mask function (Input enable control)
 - Data skipping function (Output enable control)
 - Self refresh (No refresh control is required)
 - Package options:
 - 44-pin 400 mil plastic TSOP (Type II) (TSOP144-P-400-0.80-K) (Product : MSM5412222A-xxTS-K)
 - 40-pin 400 mil plastic SOJ (SOJ40-P-400-1.27) (Product : MSM5412222A-xxJS)
- xx indicates speed rank.

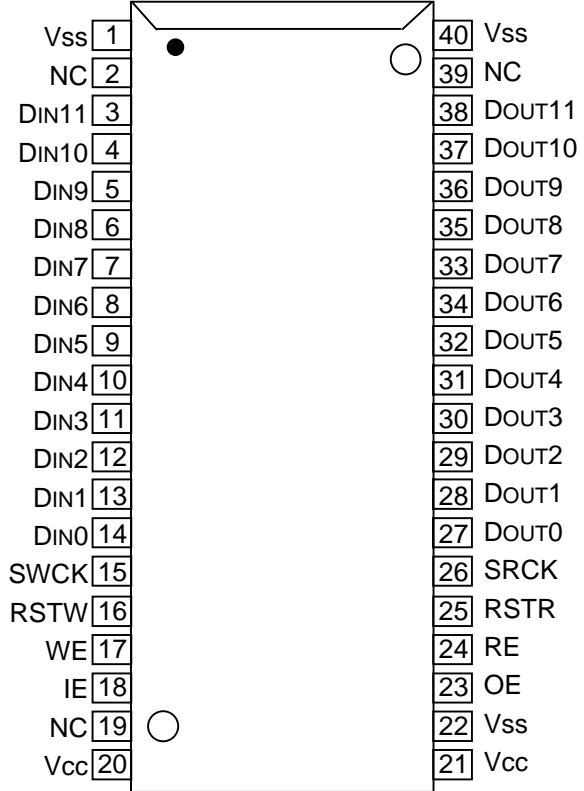

PRODUCT FAMILY

Family	Access Time(Max.)	Cycle Time(Min.)	Package
MSM5412222A-25TS-K	23ns	25ns	400 mil 44-Pin TSOP(II)
MSM5412222A-30TS-K	25ns	30ns	
MSM5412222A-25JS	23ns	25ns	400 mil 40-pin SOJ
MSM5412222A-30JS	25ns	30ns	

PIN CONFIGURATION(TOP VIEW)

44-PIN Plastic TSOP(II)
(K Type)

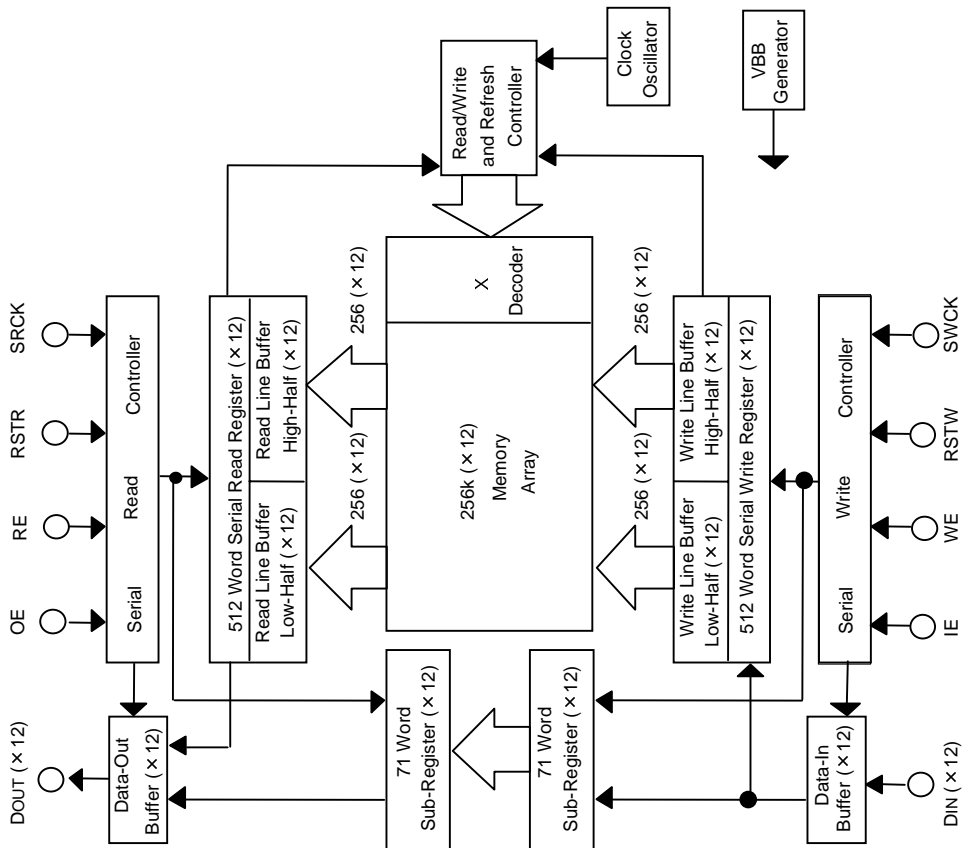

40-PIN Plastic SOJ

Pin Name	Function
SWCK	Serial Write Clock
SRCK	Serial Read Clock
WE	Write Enable
RE	Read Enable
IE	Input Enable
OE	Output Enable
RSTW	Write Reset Clock
RSTR	Read Reset Clock
DIN0-11	Data Input
DOUT0-11	Data Output
Vcc	Power Supply(5V)
Vss	Ground(0V)
NC	No Connection

NOTE:The same power supply voltage must be provided to every Vccpin, and the same GND voltage level must be provided to every Vss pin.

BLOCK DIAGRAM

OPERATION

Write Operation

The write operation is controlled by three clocks, SWCK, RSTW, and WE. Write operation is accomplished by cycling SWCK, and holding WE high after the write address pointer reset operation or RSTW.

Each write operation, which begins after RSTW, must contain at least 80 active write cycles, i.e. SWCK cycles while WE is high. To transfer the last data to the DRAM array, which at that time is stored in the serial data registers attached to the DRAM array, an RSTW operation is required after the last SWCK cycle.

Note that every write timing of MSM5412222A is delayed by one clock compared with read timings for easy cascading without any interface delay devices.

Write Reset : RSTW

The first positive transition of SWCK after RSTW becomes high resets the write address counters to zero. RSTW setup and hold times are referenced to the rising edge of SWCK. Because the write reset function is solely controlled by the SWCK rising edge after the high level of RSTW, the states of WE and IE are ignored in the write reset cycle.

Before RSTW may be brought high again for a further reset operation, it must be low for at least two SWCK cycles.

Data Inputs : D_{IN} 0 - 11

Write Clock : SWCK

The SWCK latches the input data on chip when WE is high, and also increments the internal write address pointer. Data-in setup time t_{DS} , and hold time t_{DH} are referenced to the rising edge of SWCK.

Write Enable : WE

WE is used for data write enable/disable control. WE high level enables the input, and WE low level disables the input and holds the internal write address pointer. There are no WE disable time (low) and WE enable time (high) restrictions, because the MSM5412222A is in fully static operation as long as the power is on. Note that WE setup and hold times are referenced to the rising edge of SWCK.

Input Enable : IE

IE is used to enable/disable writing into memory. IE high level enables writing. The internal write address pointer is always incremented by cycling SWCK regardless of the IE level. Note that IE setup and hold times are referenced to the rising edge of SWCK.

Read Operation

The read operation is controlled by three clocks, SRCK, RSTR, and RE. Read operation is accomplished by cycling SRCK, and holding RE high after the read address pointer reset operation or RSTR.

Each read operation, which begins after RSTR, must contain at least 80 active read cycles, i.e. SRCK cycles while RE is high.

Read Reset : RSTR

The first positive transition of SRCK after RSTR becomes high resets the read address counters to zero. RSTR setup and hold times are referenced to the rising edge of SRCK. Because the read reset function is solely controlled by the SRCK rising edge after the high level of RSTR, the states of RE and OE are ignored in the read reset cycle.

Before RSTR may be brought high again for a further reset operation, it must be low for at least *two SRCK cycles.

Data Out : DOUT 0 - 11

Read Clock : SRCK

Data is shifted out of the data registers. It is triggered by the rising edge of SRCK when RE is high during a read operation. The SRCK input increments the internal read address pointer when RE is high.

The three-state output buffer provides direct TTL compatibility (no pullup resistor required). Data out is the same polarity as data in. The output becomes valid after the access time interval t_{AC} that begins with the rising edge of SRCK. *There are no output valid time restriction on MSM5412222A.

Read Enable : RE

The function of RE is to gate of the SRCK clock for incrementing the read pointer. When RE is high before the rising edge of SRCK, the read pointer is incremented. When RE is low, the read pointer is not incremented. RE setup times (t_{RENS} and t_{RDSS}) and RE hold times (t_{RENH} and t_{RDSh}) are referenced to the rising edge of the SRCK clock.

Output Enable : OE

OE is used to enable/disable the outputs. OE high level enables the outputs. The internal read address pointer is always incremented by cycling SRCK regardless of the OE level. Note that OE setup and hold times are referenced to the rising edge of SRCK.

Power-up and Initialization

On power-up, the device is designed to begin proper operation after at least 100 us after Vcc has stabilized to a value within the range of recommended operating conditions. After this 100 us stabilization interval, the following initialization sequence must be performed. Because the read and write address counters are not valid after power-up, a minimum of 80 dummy write operations (SWCK cycles) and read operations (SRCK cycles) must be performed, followed by an RSTW operation and an RSTR operation, to properly initialize the write and the read address pointer. Dummy write cycles/RSTW and dummy read cycles/RSTR may occur simultaneously.

If these dummy read and write operations start while Vcc and/or the substrate voltage has not stabilized, it is necessary to perform an RSTR operation plus a minimum of 80 SRCK cycles plus another RSTR operation, and an RSTW operation plus a minimum of 80 SRCK cycles plus another RSTW operation to properly initialize read and write address pointers.

Old/New Data Access

There must be a minimum delay of 600 SWCK cycles between writing into memory and reading out from memory. If reading from the first field starts with an RSTR operation, before the start of writing the second field (before the next RSTW operation), then the data just written will be read out.

The start of reading out the first field of data may be delayed past the beginning of writing in the second field of data for as many as 70 SWCK cycles. If the RSTR operation for the first field read-out occurs less than 70 SWCK cycles after the RSTW operation for the second field write-in, then the internal buffering of the device assures that the first field will still be read out. The first field of data that is read out while the second field of data is written is called "old data".

In order to read out "new data", i.e., the second field written in, the delay between an RSTW operation and an RSTR operation must be at least 600 SRCK cycles. If the delay between RSTW and RSTR operations is more than 71 but less than 600 cycles, then the data read out will be undetermined. It may be "old data" or "new" data, or a combination of old and new data. Such a timing should be avoided.

Cascade Operation

The MSM5412222A is designed to allow easy cascading of multiple memory devices. This provides higher storage depth, or a longer delay than can be achieved with only one memory device.

ELECTRICAL CHARACTERISTICS

Absolute Maximum Ratings

Parameter	Symbol	Condition	Rating	Unit
Input Output Voltage	V_T	at $T_a=25^\circ\text{C}$, V_{SS}	-1.0 to 7.0	V
Output Current	I_{OS}	$T_a=25^\circ\text{C}$	50	mA
Power Dissipation	P_D	$T_a=25^\circ\text{C}$	1	W
Operating Temperature	T_{OPR}	-	0 to 70	$^\circ\text{C}$
Storage Temperature	T_{STG}	-	-55 to 150	$^\circ\text{C}$

Recommended Operating Conditions

Parameter	Symbol	Min.	Typ.	Max.	Unit

Transition Time(Rise and Fall)	t _T	3	30	3	30	ns

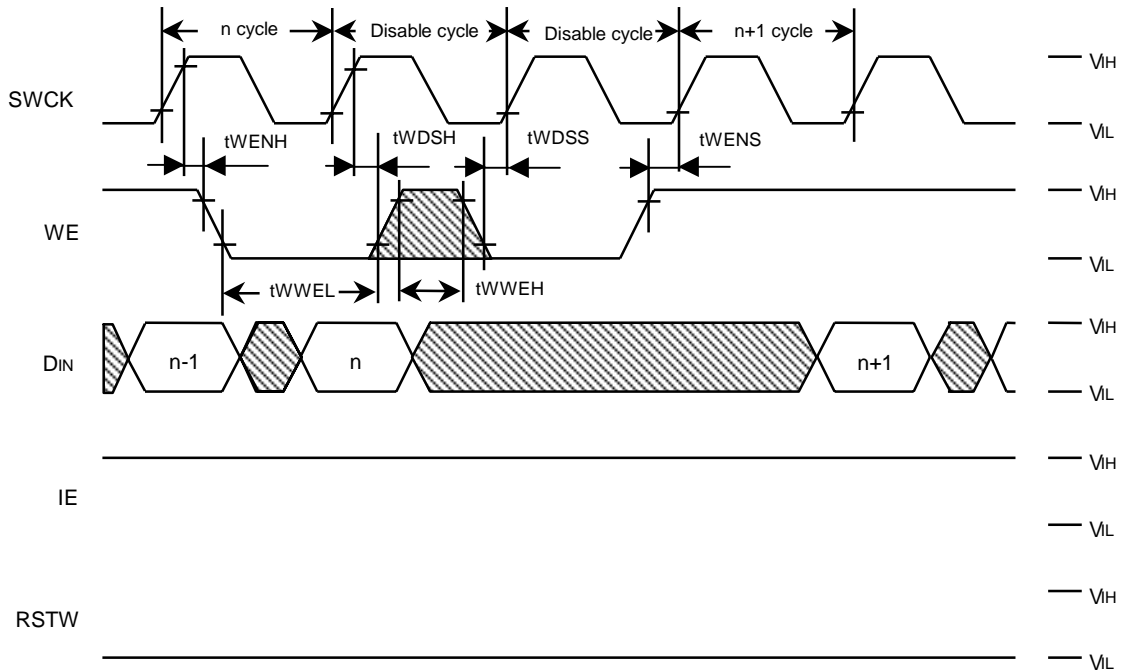

- Notes:
1. Input signal reference levels for the parameter measurement are $V_{IH} = 3.0\text{ V}$ and $V_{IL} = 0\text{ V}$.
The transition time t_r is defined to be a transition time that signal transfers between $V_{IH} = 3.0\text{ V}$ and $V_{IL} = 0\text{ V}$.
 2. AC measurements assume $t_r = 3\text{ ns}$.
 3. Read address must have more than a 600 address delay than write address in every cycle when asynchronous read/write is performed.
 4. Read must have more than a 600 address delay than write in order to read the data written in a current series of write cycles which has been started at last write reset cycle: this is called "new data read".
When read has less than a 70 address delay than write, the read data are the data written in a previous series of write cycles which had been written before at last write reset cycle: this is called "old data read".
 5. When the read address delay is between more than 71 and less than 599, read data will be undetermined. However, normal write is achieved in this address condition.
 6. Outputs are measured with a load equivalent to 1 TTL load and 30 pF. Output reference levels are $V_{OH} = 2.0\text{ V}$ and $V_{OL} = 0.8\text{ V}$.
