## Rail-To-Rail Operational Amplifiers with Enable Feature

The MC33206/7 family of operational amplifiers provide rail-to-rail operation on both the input and output. The inputs can be driven as high as 200 mV beyond the supply rails without phase reversal on the outputs and the output can swing within 50 mV of each rail. This rail-to-rail operation enables the user to make full use of the supply voltage range available. It is designed to work at very low supply voltages ( $\pm 0.9$  V) yet can operate with a single supply of up to 12 V and ground. Output current boosting techniques provide a high output current capability while keeping the drain current of the amplifier to a minimum.

The MC33206/7 has an enable mode that can be controlled externally. The typical supply current in the standby mode is  $< 1.0 \mu\text{A}$  ( $V_{\text{Enable}} = \text{Gnd}$ ). The addition of an enable function makes this amplifier an ideal choice for power sensitive applications, battery powered equipment (instrumentation and monitoring), portable telecommunication, and sample-and-hold applications.

- Standby Mode ( $I_D \leq 1.0 \mu\text{A}$ , Typ)
- Low Voltage, Single Supply Operation (1.8 V and Ground to 12 V and Ground)
- Rail-to-Rail Input Common Mode Voltage Range
- Output Voltage Swings within 50 mV of both Rails
- No Phase Reversal on the Output for Over-Driven Input Signals
- High Output Current ( $I_{SC} = 80 \text{ mA}$ , Typ)
- Low Supply Current ( $I_D = 0.9 \text{ mA}$ , Typ)
- 600  $\Omega$  Output Drive Capability
- Typical Gain Bandwidth Product = 2.2 MHz

## MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Supply Voltage ( $V_{CC}$ to $V_{EE}$ )	$V_S$	13	V
ESD Protection Voltage at any Pin Human Body Model	$V_{ESD}$	2,000	V
Voltage at any Device Pin	$V_{DP}$	$V_S \pm 0.5$	V
Input Differential Voltage Range	$V_{IDR}$	(Note 1)	V
Common Mode Input Voltage Range (Note 2)	$V_{CM}$	$V_{CC} + 0.5$ to $V_{EE} - 0.5$	V
Output Short Circuit Duration (Note 3)	$t_s$	(Note 3)	sec
Maximum Junction Temperature	$T_J$	+150	°C
Storage Temperature Range	$T_{stg}$	-65 to +150	°C
Maximum Power Dissipation	$P_D$	(Note 3)	mW

- NOTES:**
1. The differential input voltage of each amplifier is limited by two internal parallel back-to-back diodes. For additional differential input voltage range, use current limiting resistors in series with the input pins.
  2. The common-mode input voltage range of each amplifier is limited by diodes connected from the inputs to both power supply rails. Therefore, the voltage on either input must not exceed either supply rail by more than 500 mV.
  3. Power dissipation must be considered to ensure maximum junction temperature ( $T_J$ ) is not exceeded.
  4. ESD data available upon request.

**GENERAL INFORMATION**

The MC33206/7 family of operational amplifiers are unique in their ability to swing rail-to-rail on both the input and the output with a completely bipolar design. This offers low noise, high output current capability and a wide common mode input voltage range even with low supply voltages. Operation is guaranteed over an extended temperature range and at supply voltages of 2.0 V, 3.3 V and 5.0 V and ground.

Since the common mode input voltage range extends from  $V_{CC}$  to  $V_{EE}$ , it can be operated with either single or split voltage supplies. The MC33206/7 are guaranteed not to latch or phase reverse over the entire common mode range, however, the inputs should not be allowed to exceed maximum ratings.

**CIRCUIT INFORMATION**

Rail-to-rail performance is achieved at the input of the amplifiers by using parallel NPN-PNP differential input stages. When the inputs are within 800 mV of the negative rail, the PNP stage is on. When the inputs are more than 800 mV greater than  $V_{EE}$ , the NPN stage is on. This switching of input pairs will cause a reversal of input bias currents (see Figure 6). Also, slight differences in offset voltage may be noted between the NPN and PNP pairs. Cross-coupling techniques have been used to keep this change to a minimum.

In addition to its rail-to-rail performance, the output stage is current boosted to provide 80 mA of output current, enabling the op amp to drive 600  $\Omega$  loads. Because of this high output current capability, care should be taken not to exceed the 150°C maximum junction temperature.

**Enable Function**

The MC33206/07 enable pins allow the user to externally control the device. (Refer to the Pin Diagram on the first page of this data sheet for enable pin connections.) If the enable pins are pulled low (Gnd) each amplifier (MC33206) and amplifier pair (MC33207) will be disabled. When the enable pins are at a logic high ( $V_{Enable} \geq V_{EE} = 1.8 V$ ) the amplifiers will turn "on". Refer to the data sheet characteristics for the required levels needed to change logical state.

The time to change states (from device "on" to "off" and "off" to "on") is defined as the time delay. The Circuit in Figure 27 is used to measure  $t_{on}$  and  $t_{off}$ . Typical  $t_{on}$  and  $t_{off}$  measurements are shown in Figures 28 and 29. When the device is turned off ( $V_{Enable} = Gnd$ ) an internal regulator is shut off disabling the amplifier.

Figure 27. Test Circuit for  $t_{on}$  and  $t_{off}$

Figure 28.  $t_{on}$  Response

Figure 29.  $t_{off}$  Response

**Low Voltage Operation**

The MC33206/07 will operate at supply voltages down to 1.8 V and ground. Since this device is a rail-to-rail on both the input and output, one can be assured of continued operation in battery applications when battery voltages drop to low voltage levels. This is called End of Discharge (see Figure 30). Now, the user can select a minimum quantity of batteries best suited for the particular design depending on the type of battery chosen. This will minimize part count in many designs.

Figure 30. Typical Battery Characteristics

Type	Operating Voltage	End of Discharge
Alkaline	1.5 V	0.9 V
NiCd	1.2 V	1.0 V
NiMh	1.2 V	1.0 V
Silver Oxide	1.6 V	1.3 V
Lithium Ion	3.6 V	2.5 V

**Compensating for Output Capacitance**

The combination of device output impedance and increasing capacitive loading will cause phase delay (reducing the phase margin) in any amplifier (Figure 22). If the loading is excessive, the resulting response can be circuit oscillation. In other words, an amplifier can become unstable when the phase becomes greater than 180 degrees before the open loop gain drops to unity gain. Figures 18 and 19 show this situation as frequency increases for a given load. The MC33206/7 can typically drive up to 300 pF loads at unity gain without oscillating.

## MC33206 MC33207

Figure 31. Capacitive Loads Compensation

There are several ways to compensate for this phenomena. Adding series resistance to the output is one way, but not an ideal solution. A dc voltage error will occur at the output. A better design solution to compensate for higher capacitive loads would be to use the circuit in Figure 31. This design helps to counteract the loss of phase margin by taking the high frequency output signal and feeding it back into the amplifier inverting input. This technique helps to overcome oscillation due to a highly capacitive load. Keep in mind that compensation will have the affect of lowering the Gain Bandwidth Product (GPW). The values of  $C_X$  and  $R_O$ , are determined experimentally. Typical  $C_X$  and  $C_L$  will be the same value.

### SPICE Model

If a SPICE Macromodel is desired for the MC33206/07, the user can define the characteristics from the following information. Obtain the SPICE Macromodel for the MC33204 Rail-to-Rail Operational Amplifier (device is the same as the MC33207). For the Enable feature of the MC33207, simulate it as a bipolar switch. The Macromodel does not include an input capacitance between the inverting and noninverting inputs. This capacitor is called  $C_{in}$ . Add 3.0 to 5.0 pF if stability analysis is required.
