

FEATURES

- Single full-duplex asynchronous channel
- 128-byte deep transmitter / receiver FIFO
- Fully software compatible with industry standard 16C550 type UARTs
- Readable FIFO levels
- System clock up to 60MHz at 5V, 50 MHz at 3.3V
- Flexible clock prescaler from 1 to 31.875
- 9-bit data framing as well as 5,6,7 and 8
- Detection of bad data in the receiver FIFO
- Automated in-band flow control using programmable Xon/Xoff characters
- Transmitter and receiver can be disabled
- Low power CMOS
- 3.3V / 5V operation

DESCRIPTION

The OXCF950 is a low cost asynchronous 16-bit PC card (henceforth referred to as PCMCIA) or Compact Flash (henceforth referred to as CF) UART (and Local Bus) device. Local Bus Selection is performed by use of a MODE pin. Note that Local Bus mode uses indirect addressing, which is only supported by PCMCIA.

The 3.3V/5V technology has been selected to allow the device to be used in both high and low voltage environments, as stated in the PCMCIA specification. Note that when the OXCF950 is operating at 3.3V, its I/O is not 5V tolerant.

The EEPROM interface allows the programming of the Attribute Memory, UART and Local Configuration Registers during power up or hard/soft reset. This allows different card manufacturers to modify the information contained in the Attribute memory or UART/registers as required, for example PC-Card ID value.

A number of power-down modes are included to keep power consumption to a minimum. Such features include clock division (fully programmable) and sleep modes when a function of the OXCF950 is not being used.

The OXCF950 contains a single-channel ultra-high performance UART offering data rates up to 15Mbps (at 5V) and 128-deep transmitter and receiver FIFOs. Deep FIFOs reduce CPU overhead and allow utilisation of higher data rates.

Oxford Semiconductor Ltd.
25 Milton Park, Abingdon, Oxon, OX14 4SH, UK
Tel: +44 (0)1235 824900

- Programmable by external Microwire[™] EEPROM (EEPROM programmed via Oxford Semiconductor utilities).
- Extremely low power consumption by use of asynchronous UART core and power down (sleep) modes
- Ultra small 48 pin TQFP package.
- Supports all UART types 450 up to 950 (fully programmable)
- CF+ Compliant (Revision 1.4).
- 16-bit PC Card Compliant (PCMCIA Revision 7.1)
- 8 bit Local Bus interface included for PCMCIA applications
- 2 Multi-purpose I/O pins which can be configured as interrupt inputs

It is software compatible with the widely used industrystandard 16C550 type devices and compatibles, as well as other OX16C95x family devices.

In addition to increased performance and FIFO size, the OXCF950 also provides enhanced features including improved flow control. Automated software flow control using Xon/Xoff and automated hardware flow control using CTS#/RTS# and DSR#/DTR# prevent FIFO over-run. Flow control and interrupt thresholds are fully programmable and readable, enabling programmers to fine-tune the performance of their system. FIFO levels are readable to facilitate fast driver applications.

The addition of software reset enables recovery from unforeseen error conditions allowing drivers to restart gracefully. The OXCF950 supports 9-bit data frames used in multi-drop industrial protocols. It also offers multiple external clock options for isochronous applications, e.g. ISDN, xDSL.

The OXCF950 also incorporates a bridge to an 8 bit Local Bus in Local Bus Mode. It allows card developers to expand the capabilities of their products by adding peripherals to this bus. In addition, two user IO pins are included to enhance external device control. These IO pins can also be configured as interrupt inputs.

3 PIN DESCRIPTIONS

Pin Number	Dir ¹	Name	Description
CF/PCMCIA Interface and Contro		Indific	Description
	I T -	4 10 01	
46, 45, 43, 42		A[3:0]	PCMCIA/CF address bus, bits [3:0]
6, 7, 10, 11, 12, 37, 38, 41	I/O	D[7:0]	PCMCIA/CF data bi-directional bus.
44	IU	REG#	Register select and I/O enable
5	IU	CE[1]#	Active low card enable
4	1	OE#	Active low memory read enable
1		WE#	Active-low write enable used for strobing Memory Write data
			(Attribute memory).
3	IU	IORD#	Active-low I/Oread enable
2	IU	IOWR#	Active-low I/O write enable
32	0	WP	Write protect (in Memory only mode)
	0	IOIS16#	Data is 16 bit (in IO and Memory mode)
47	IU	RESET	PCMCIA/CF Reset
48	0	READY#	Device ready (in Memory only mode)
		IREQ#	Active-low Interrupt request (in IO and Memory mode).
UART / Local Bus Function			
24	0	SOUT	UART serial data output.
		IrDA_Out	UART IrDA data output when MCR[6] is set in enhanced mode.

OXCF950 DATA SHEET V1.1

23	1	SIN	UART serial data input.
		lrDA_In	UART IrDA data input when IrDA mode is enabled (see above).
29	1	DCD#	Active-low modem data-carrier-detect input.
26	0	DTR#	Active-low modem data-terminal-ready output. If automated DTR# flow control is enabled, the DTR# pin is asserted and de-asserted if the receiver FIFO reaches or falls below the programmed thresholds, respectively.
		485_En	In RS485 halfduplex mode, the DTR# pin may be programmed to reflect the state of the transmitter empty bit to automatically control the direction of the RS485 transceiver buffer (see register ACR[4:3]).
		Tx_Clk_Out	Transmitter 1x clock (baud rate generator output). For isochronous applications, the 1x (or Nx) transmitter clock may be asserted on the DTR# pin (see register CKS[5:4]).
25	0	RTS#	Active-low modem request to-send output. If automated RTS# flow control is enabled, the RTS# pin is de-asserted and reasserted whenever the receiver FIFO reaches or falls below the programmed thresholds, respectively.
27	I	CTS#	Active-low modem clear-to-send input. If automated CTS# flow control is enabled, upon de-assertion of the CTS# pin, the transmitter will complete the current character and enter the idle mode until the CTS# pin is reasserted. Note: flow control characters are transmitted regardless of the state of the CTS# pin.
28	1	DSR#	Active-low modem data-set ready input. If automated DSR# flow control is enabled, upon de-assertion of the DSR# pin, the transmitter will complete the current character and enter the idle mode until the DSR# pin is reasserted. Note: flow control characters are transmitted regardless of the state of the DSR# pin
		Rx_Clk_In	External receiver clock for isochronous applications. The Rx_Clk_In is selected when register CKS[1:0] = '01'
30		RI#	Active-low modem Ring-indicator input
		Tx_Clk_In	External transmitter clock. This clock can be used by the transmitter (and indirectly by the receiver) when register CKS[6] = '1'.
21	0	XTLO	Crystal oscillator output
20	I	XTLI	Crystal oscillator input or external clock pin. Frequency 1.8MHz -> 60MHz
34	0	LBCS#	Local Bus Mode : Active low local bus Chip select
	1	A[5]	Normal Mode : Address bit 5
35	0	LBRD#2	Local Bus Mode : Active-low local bus read enable
		A[6]	Normal Mode : Address bit 6

4 CONFIGURATION & OPERATION

PCMCIA and CF host systems allow for hot insertion of cards.

Once a card has been inserted into a host system, the host system will configure it. The PCMCIA standard defines two card detect pins, that allow the host to be notified when a card is inserted or removed.

By default the device will power up in either Normal or Local Bus mode, depending on the mode pin. The difference between these two modes is given in the following table. Note that the Local Bus mode is not suitable for CF systems.

Normal Mode (MODE=0)	Local Bus Mode (MODE=1)
Address bus is 8 bits wide.	Address bus is 4 bits wide.
Indirect access is not used.	Indirect access is used.
No external local bus.	External local bus supported.

Table 2: Differences between Normal & Local Bus Mode

The host system will wait for the READY# signal to be active before reading the Card Information Structure, given in attribute memory within the device. By reading this tuple information, the host system is able to identify the device type and the necessary resources requested by the device.

The host system will then load the device-driver software according to this information and will configure the IO, memory and interrupt resources. After determining that the device is a memory and IO type device the host will enable

it's IO mode by writing to the device's Configuration Options Register in attribute memory space. Device drivers can then access the functions at the assigned addresses.

A set of local configuration registers have been provided that can be used to control the device's characteristics (such as interrupt handling) and report internal functional status. These registers can be accessed in IO space, utilising the same IO space as the local bus (Local Bus mode only) and are situated above the UART registers. These local registers can be set up by device drivers or from the optional EEPROM.

The EEPROM can also be used to redefine the reset values of all register areas to tailor the device to the end users requirements if the default values do not meet the specific requirements of the manufacturer. This reprogramming of the device can also be performed for the CIS area, allowing the manufacturer to modify resources required, or Manufacturer ID values for example. As an additional enhancement, the EEPROM can be used to preprogram the UART, allowing pre-configuration, without requiring device driver changes. This allows the enhanced features of the integrated UART to be in place prior to handover to any generic device drivers.

Note that a default set of tuples is provided for both operating modes thus allowing for a single chip solution in either mode.

5 PCMCIA / CF TARGET CONTROLLER

5.1 Operation

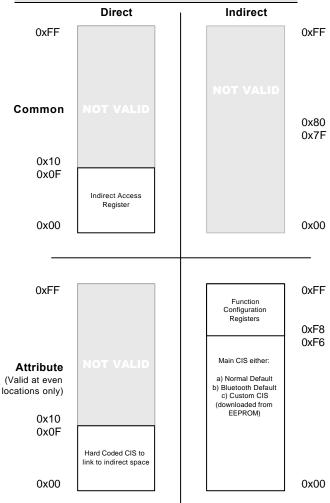

Note: See section 10 for timing waveforms.

The OXCF950 responds to a number of different CF/PCMCIA accesses (detailed below). Section 11 contains timing diagrams and information for each of these types of access.

- Direct Common Memory read/writes: These are required in Local Bus mode only to allow indirect access to attribute memory. This type of access is permitted before and after configuration to allow the reading of the CIS information, but is only supported by the PCMCIA specification. Only 8 bit data, even byte accesses are performed to this memory as it is only used for access to the indirect attribute memory. If the host attempts to access an invalid address, the value of 0xFF (null) is returned.
- Direct Attribute Memory read/writes: Access to direct attribute memory is required in both CF and PCMCIA specifications. This memory space contains all the configuration information for the device, as well as the configuration registers. In CF systems, where only direct access is permitted, this space is the only memory space that is accessed by the host system. If the host attempts to access common memory in this mode, the device will return 0xFF telling the host that there is no valid data in this space. In Local Bus Mode, the direct attribute memory informs the host that indirect access is enabled allowing the host to perform indirect access to attribute memory, via common memory. Valid data is 8 bits wide and on even bytes only, for direct attribute memory (as defined in the PCMCIA 7.1 standard)
- Indirect Attribute Memory read/writes (Local Bus mode only): Access to indirect attribute memory is performed through direct common memory. This allows the device to provide full functionality with only 4 address pins. This access is performed to read the CIS and also read/write to configuration registers. Valid data is 8 bit wide and on even bytes only, for indirect attribute memory (as defined in the PCMCIA 7.1 standard).
- IO read/writes: IO accesses are performed to access the UART, local bus (Local Bus mode) and local configuration registers. Data width is restricted to 8 bits, as required by the standard UART function. As the device CIS information configures the card as a single function device, no base addresses need to be

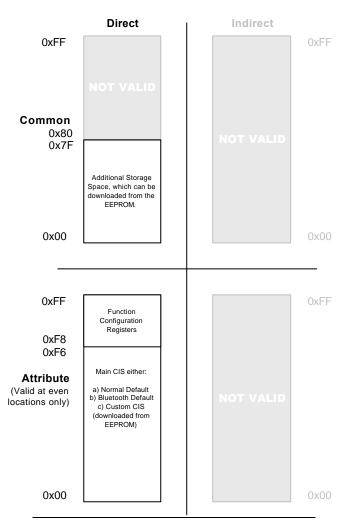

defined thus simplifying access to the function. As reads and writes are immediate, there is no requirement to hold the WAIT# signal in its active state, thus providing maximum speed access to IO space.

5.2 Configuration Space (Card Information Structure)

5.2.1 Local Bus Mode Space Map

Figure 3: Local Bus mode memory space map

5.2.2 Normal Mode Space Map

Figure 4: Normal Mode memory space map

5.3 Access to IO Function

5.3.1 Access to Internal UART

Access to the internal UART is achieved via standard IO mapping. As the device is configured as a single function device, no base address is required to access the UART. As IO mapping is used, access to the UART is permitted only after the card has been configured. Once the Configuration Options Register has been set in the Attribute area, the UART can be accessed following the mapping shown in Table 3.

OXCF950 DATA SHEET V1.1

UART Address (hex)	CF/PCMCIA offset from address 0 for UART function in IO space (hex)
0	0
1	1
2	2
3	3
4	4
5	5
6	6
7	7

Table 3: UART's mapping in I/O space

5.3.2 Access to Local Bus

Access to the internal Local Bus is achieved via standard IO mapping. The Local Bus function is available in Local Bus mode only as it's device pins are used as the extended address bits required for direct access in Normal mode. Indirect access is only supported in the PCMCIA specification, so the local bus is only available in PCMCIA systems. As the device is configured as a single function device, no base address is required to access the Local Bus. As IO mapping is used, access to the Local Bus is permitted only after the card has been configured. Once the Configuration Options Register has been set in the Attribute area, the Local Bus can be accessed following the mapping shown in table Table 4. This access is permitted only if bit[0] is reset to '0' in the MDR register in the UART, otherwise the local configuration registers will be accessed rather than the local bus.

Local Bus Address ¹ (hex)	CF/PCMCIA offset from address 0 for Local Bus function in IO space (hex)
0	8
1	9
2	A
3	В
4	С
5	D
6	E
7	F

Table 4: Local Bus mapping in I/O space

Note t Although only 4 bits of IO address space are requested by the default CIS in the device, the address range may be extended past these four bits. This can be achieved by modifying the CIS, via the EEPROM, and connecting the extended address bits to the external local bus device.

5.3.3 Accessing Local Configuration Registers

The local configuration registers are a set of device specific registers, which can be accessed via standard IO mapping. As the device is configured as a single function device, no base address is required to access the local configuration registers. Since IO mapping is used, access to the local configuration registers is permitted only after the card has been configured. Once the Configuration Options Register has been set in the Attribute area, the local configuration registers can be accessed following the mapping shown in Table 5. This access is always permitted in Normal Mode. In Local Bus Mode access is only permitted if bit[0] is set to '1' in the MDR register in the UART, otherwise the local bus will be accessed rather than the local configuration registers.

CF/PCMCIA offset from address 0 for local configuration registers in IO space (hex)	Register Map
8	EEPROM Status and Control register
9	Multi-Purpose I/O Configuration register

E	Reserved
F	Reserved

Table 5: Local Configuration Register's mapping in I/O space

Each of the local configuration registers are explained in the following sections

EEPROM Status and Control register 'ESC'(Offset 0x08)

This register defines the control on the serial EEPROM. The individual bits are described in Table 6.

Bits	Description	Read/	Write	Reset
		EEPROM	PCMCIA	
7:5	Reserved	-	R	000
4	EEPROM Data In For reads from the EEPROM this input bit is the output data (DO) of the external EEPROM connected to EE_DI pin	-	R	Х
3	EEPROM Data Out. For writes to the EEPROM, this output bit feeds the inputdata of the external EEPROM (DI). This bit is output on the devices EE_DO and clocked into the EEPROM by EE_CK	-	R/W	0
2	EEPROM Clock. For reads or writes to the external EEPROM toggle this bit to generate an EEPROM clock (EE_CK pin)	-	R/W	0
1	EEPROM Chip Select. When '1' the EEPROM chip select pin EE_CS is activated (high). When '0' EE_CS is de-activated (low)	-	R/W	0
0	EEPROM Valid A '1' indicates that a valid EEPROM program header is present	-	R	Х

Table 6: EEPROM Status and Control Register

Multi-Purpose I/O Configuration register 'MIC' (Offset 0x09)

This register configures the operation for the multi-purpose I/O pins 'MIO[1:0]' as follows

Bits	Description	Read/Write				
		EEPROM	PCMCIA			
7:4	Reserved	-	R	0000		
3:2	MIO1 Configuration register 00 -> MIO1 is a non-inverting input pin 01 -> MIO1 is an inverting input pin 10 -> MIO1 is an output pin driving '0' 11 -> MIO1 is an output pin driving '1'	W	R/W	00		
1:0	MIO0 Configuration register 00 -> MIO0 is a non-inverting input pin 01 -> MIO0 is an inverting input pin 10 -> MIO0 is an output pin driving '0' 11 -> MIO0 is an output pin driving '1'	W	R/W	00		

Table 7: Multi Purpose I/O Configuration Register

UART Divider/Interrupt Pulse Width Divider register 'DIV' (Offset 0x0A)

This register defines the divide values (2^N division) for the clocks to the UART and Interrupt pulse generator signal. This allows the device to be set up in its lowest power mode possible, and is fully programmable by the host or the EEPROM. The default value for the UART clock divider provides a clock to the UART of x1. The default value for the Interrupt pulse divider provides a clock to the interrupt processor of /32. See Section 5.4.1 Note that the UART clock rate should not be changed without then resetting the UART (see SRT register).

Bits	Description	Read/	Write	Reset
		EEPROM	PCMCIA	
7:6	Reserved	-	R	00
5:3	Uart clock divide value. The division ratio is 2 ^N , giving 1, 2, 4, 8, 16, 32, 64, 128	W	R/W	000
2:0	Interrupt Pulse divide value: This field should be set under the following clock freq. conditions 000 -> when clock frequency is less than 2MHz 001 -> when clock frequency is between 2 and 4MHz 010 -> when clock frequency is between 4 and 8MHz 011 -> when clock frequency is between 8 and 16MHz 100 -> when clock frequency is between 16 and 32MHz 101 -> when clock frequency is between 32 and 64MHz 110 -> RESERVED 111 -> RESERVED	W	R/W	101

Table 8: UART Divider/ Interrupt Pulse Width Divider

Mode Status register 'MSR' (Offset 0x0B)

This read only register return the state of the MODE pin (i.e. whether in Normal or Local Bus modes).

Bits	Description Read/Write		Write	Reset
		EEPROM	PCMCIA	
7:1	Reserved	-	R	0000000
0	Mode O = Normal, 1 = Local Bus	-	R	Х

Table 9: Mode Status Register

Interrupt Status and Control register 'ISR' (Offset 0x0C)

This register controls the assertion of interrupts from the User I/O pins (MIO[1:0]) as well as returning the internal status of the interrupt sources.

Bits	Description	Read/	Write	Reset
		EEPROM	PCMCIA	
7:5	Reserved	-	R	000
4	UART Interrupt status This bit reflects the state of the internal UART interrupt	-	R	0
3	MIO[1] interrupt mask When set to '1' allows pin MIO[1] to assert an interrupt on the devices IREQ# pin. The state of the MIO[1] signal that causes an interrupt is dependent upon the polarity set by the register fields MIC[3:2].	W	R/W	0
2	MIO[0] interrupt mask When set to '1' allows pin MIO[0] to assert an interrupt on the devices IREQ# pin. The state of the MIO[0] signal that causes an interrupt is dependent upon the polarity set by the register fields MIC[1:0].	W	R/W	0
1	MIO1 Internal state This bit reflects the state of the internal MIO[1]. The internal MIO[1] signal reflects the non-inverted or inverted state of MIO[1] pin	-	R	Х
0	MIO0 Internal state This bit reflects the state of the internal MIO[0]. The internal MIO[0] signal reflects the non-inverted or inverted state of MIO[0] pin	-	R	Х

Table 10: Interrupt Status Register

Soft UART/Local Bus reset register 'SRT' (Offset 0x0D)

This register controls the soft reset passed to the UART and local bus reset. These reset lines are in addition to the soft reset that may be produced by the host (bit[7] of the COR register in attribute memory space). Note that the local bus reset is used in Local Bus mode only and not in Normal mode. Note these bits are not selfclearing.

Bits	Description	Read/	Reset	
		EEPROM	PCMCIA	
7:2	Reserved	-	R	000000
1	Active high soft reset for UART	W	R/W	0
0	Active high soft reset for Local Bus	W	R/W	0

Table 11: Soft UART / Local Bus Reset (LB reset used in Local Bus Mode only)

5.4 CF / PCMCIA Interrupt

5.4.1 Interrupt Generation

PCMCIA/CF cards support pulse or level type interrupt signals to request interrupt service from the host system. The CIS of the card specifies whether pulse, level or both types of interrupt can be generated. Once the host has read the CIS it is able to set the LevIReq field in the Configuration Options Register (COR) to tell the card which type of interrupts should be generated.

The OXCF950 is capable of generating either type of interrupt. However, to reduce power consumption, the default CIS states that only level type interrupts can be generated. A custom CIS can be constructed that specifies the card has the ability to generate pulse type interrupts, if this is required, by using an external EEPROM.

The OXCF950 uses a programmable clock divider circuit to generate pulse type interrupts signals. The pulse that is generated is one clock cycle (after division) in length. The divider circuit can be programmed by setting the contents of the Interrupt Pulse

OXCF950 DATA SHEET V1.1

Divide Value field in the DIV local configuration register (see section 6.3.4.3). This allows the length of the pulse to be varied, so that different clock frequencies can be used and the pulse can still be kept as short as possible, without violating the minimum length of 50 μ s as defined in the PCMCIA Standard. Table 12 shows how the register should be programmed for different clock frequencies.

Clo	ck Fre	quen	су (М	Hz)	Interrupt Divider Setting
		f	<	2	000
2	<=	f	<	4	001
4	<=	f	<	8	010
8	<=	f	<	16	011

Table 12:	Interrupt	Pulse	Divide	Value settings
-----------	-----------	-------	--------	----------------

5.4.2 Interrupt Sources

The OXCF950 has three possible interrupt sources. These are the internal UART, and the two multi-purpose I/O pins, which can be configured as interrupts using the MIO Configuration Register (MIC – see section 6.3.4.2) and the Interrupt Status and Control Register (ISR – see section 6.3.4.5)

When the OXCF950 is requesting interrupt service, the Intr field within the Configuration Status Register (CSR – see section 6.5.2) will be set to 1. Otherwise this field will be cleared to 0. The Intr field value is controlled by the interrupt source (i.e UART or MIO [1:0]). The status of the actual interrupts can be read from the ISR register.

5.5 CF/PCMCIA Function Configuration Registers

Each PCMCIA/CF card's I/O function must implement Function Configuration Registers (FCR). These registers allow the host to configure the function provided by the card, and are mapped into the attribute memory space at the location specified within the CONFIG tuple (in the CIS). The CONFIG tuple defines a base address for the Function Configuration Registers and a number corresponding to how may registers are supported (4 registers in the OXCF950). Each of these registers has read/write capability and is mapped at even location, consistent with the design of attribute memory. The registers supported in the OXCF950 are shown in the following table.

Offset from FCR base address	Attribute memory address	Register
0	F8	Configuration Options Register
2	FA	Configuration and Status Register
4	FC	Pin Replacement Register
8	FE	Socket & Copy Register

Table 13: Configuration Register Mapping

Due to the type of function the OXCF950 configures the card to be, and the fact that it is a single function device, only a sub-set of the total number of configuration registers are required.

The definition of each configuration register is detailed in the next few sub-sections.

5.5.1 Configuration Options Register 'COR' (offset 0xF8)

The configuration options register is used to configure PCMCIA/CF cards that have programmable address decoders. Once the card's client driver has successfully parsed the CIS, it will attempt to obtain system resources, as requested by the CIS. On completion of this it assigns the resources to the card via the COR. The COR format and description is given in Table 14.

SRESET LevIREQ Function Configuration Index	D7	D6	D5	D4	D3	D2	D1	D0
	COLCET		Function Configuration Index					

Field	Туре	Description
SRESET	R/W	Software reset Setting this field to '1' places the card in the reset state. This is equivalent to
		setting the RESET signal (on pin) except this SRESET field is not reset. Returning this field to '0' leaves the card in the same un-configured, reset state as the card would be following a power-up and hard reset.
LevIREQ ¹	R/W	Level Mode IREQ#
		Setting this field to '1' enables level type interrupts
		Setting this field to '0' enables pulse type interrups
Function Configuration Index	R/W	Configuration Index
		The host sets this field to the value of the Configuration Entry Number field of a Configuration Table Entry tuple as defined in the CIS. On setting the non-zero value in this field the function IO is enabled and IO accesses are allowed. When the field is set to zero (e.g. after a hard reset) the card will be configured to memory only mode and all IO accesses will be ignored by the card.

Table 14: Configuration Option Register

The default tuples in the CIS tell the host that only level type interrupts are supported to allow lowest power consumption. The OXCF950 supports both level and pulse type interrupts, and if a particular manufacturer requires to use pulse type, or both, then the CIS can be modified using the external EEPROM.

5.5.2 Configuration Status Register 'CSR' (Offset 0xFA)

Note 1

The Configuration and Status Register is an optional register, supported by the OXCF950. The register allows additional control over a function's configuration and reports status related to the function's configuration.

D7	D6	D5	D4	D3	D2	D1	D0
Changed	SigChg	IOIs8	RFU	Audio	PwrDwn	Intr	IntrAck

Field	Туре	Description
Changed	R	If a PCMCIA/CF card is using the I/O interface, the functions Pin Replacement register is present and one or more of the state change signals in the Pin Replacement Register are set to one(1), or one Event bits in the Extended Status Register are set (1) and the corresponding Enable bit is set (1), the function shall set this field to one (1).
		If a PCMCIA/CF card is not using the I/O interface or the function's Pin Replacement register is not present, this field is undefined and should be ignored.
SigChg ¹	R/W	This field serves as a gate for STSCHG# If a PCMCIA/CF card is using the I/O interface and both the Changed and SigChg fields are set to one (1), the function shall assert STSCHG#.

		If a PCMCIA/CF card is using the I/O interface and this field is reset to zero (0), the function shall not assert STSCHG#. If a PCMCIA/CF card is not using the I/O interface or the function's Pin Replacement register is not present, this field is undefined and should be ignored.
IOIs8	R/W	The host sets this field to one (1) when it can provide I/O cycles only with an 8-bit D[70] data path. The card is guaranteed that accesses to the 16-bit registers will occur as two byte accesses rather than as a single 16-bit access.
RFU	-	Reserved. Must be zero (0).
Audio ²	R/W	This bit is set to one (1) to enable audio information on SPKR# when the card is configured.
PwdDwn ³	R/W	When the host sets this field to one (1), the function shall enter a power-down state, if such a state exists.If a PCMCIA/CF card function does not have a power-down state, the function shall ignore this field.
Intr	R	Interrupt Request / Acknowledge – This field reports whether the function is requesting interrupt servicing and may be used to acknowledge the host system is ready to process another interrupt request from the PCMCIA/CF card. The function shall set this field to one (1) when it is requesting interrupt service. The function shall set this field to zero (0) when it is not requesting interrupt service. Writes to this field are ignored when the IntrAck field of all Configuration and Status Registers on the PCMCIA/CF card are reset to zero (0).
IntrAck	R/W	Single function cards ignore this field on writes and always return zero (0).

Table 15: Configuration Status Register

Note 1

The STSCHG# signal is optional and is not supported on the OXCF950, to reduce the complexity of the device.

Note 2

Audio is not supported on the device.

Note 3

The OXCF950 does not support a specific power down mode, since it is a low power device that features a number of sleep modes (see Section 7 for further details).

5.5.3 Pin Replacement Register 'PRR' (Offset 0xFC)

The Pin Replacement Register is implemented to provide information about READY, WP or the BVD[2..1] status when implementing the I/O interface.

D7	D6	D5	D4	D3	D2	D1	D0
CBVD1	CBVD2	CREA DY	CWProt	RBVD1	RBVD2	RREADY	RWProt

Field	Description
CBVD1	This bit is set (1) when the corresponding bit, RBVD1, changes state. This bit may also be
	written by the host.
CBVD2	This bit is set (1) when the corresponding bit, RBVD2, changes state. This bit may also be

	written by the host.
CREADY	This bit is set (1) when the corresponding bit, RREADY, changes state. This bit may also be written by the host.
CWProt	This bit is set (1) when the corresponding bit, RWProt, changes state. This bit may also be written by the host.
RBVD1	When read, this bit represents the internal state of the Battery Voltage Detect circuits which would be on the BVD1 pin.
	When this bit is written as 1 the corresponding CBVD1 bit is also written. When this bit is written as 0, the CBVD1 bit is unaffected.
RBVD2	When read, this bit represents the internal state of the Battery Voltage Detect circuits which would be on the BVD2 pin.
	When this bit is written as 1 the corresponding CBVD2 bit is also written. When this bit is written as 0, the CBVD2 bit is unaffected.
RREADY	When read, this bit represents the internal state of the READY signal. This bit may also be used to determine the state of READY as that pin has been relocated for use as Interrupt Request on IO Cards.
	When this bit is written as 1 the corresponding "changed" bit is also written. When this bit is written as 0, the "changed" bit is unaffected.
RWProt	When read, this bit represents the state of the WP signal. This signal may also be used to determine the state of the Write Protect switch when pin 33 is being used for IOIS16#.
	When this bit is written as 1 the corresponding "changed" bit is also written. When this bit is written as 0, the "changed" bit is unaffected.

Table 16: Pin Replacement Register

5.5.4 Socket and Copy Register 'SCR' (Offset 0xFE)

This is an optional read/write register, implemented by the OXCF950, which the PCMCIA/CF card may use to distinguish between similar cards installed in a system. This register is always written by the system before writing the card's Function Configuration Index field in the Configuration Option register.

D7	D6	D5	D4	D3	D2	D1	D0
Reserved	Reserved Copy Number		Socket Number				
Field		Description					
Reserved				standardization. T	his bit must be s	et to zero (0) by	software when
		the register is					
Copy Number				te in their CIS tha			
				e a copy number	(0 to MAX twin	cards, MAX = n-	1) written back
		to the socket a	and Copy registe	er.			
		This field indicates to the card that it is the n'th copy of the card installed in the system, which is identically configured. The first card installed receives the value 0. This permits identical cards designed to share a common set of I/O ports while remaining uniquely identifiable and consecutively ordered.					
Socket Number		is numbered of		MCIA/CF card tha any cards designe tifiable.			

5.6 Card Information Structure

5.6.1 Local Bus Mode

Value (Hex)	Tuple Name	Description
Direct Attr	ibute	
0x01 0x02 0x00 0xFF	CISTPL_DEVICE	CIS should start with a CISTPL_DEVICE tuple.
0x03 0x00	CISTPL_INDIRECT	Use indirect access register (located in direct common memory).
0xFF	CISTPL_END	
Indirect At	tribute	•
0x13 0x03 0x43 0x49 0x53	CISTPL_LINKTARGET	The first tuple in indirect memory must be a CISTPL_LINKTARGET to prove that a valid CIS chain is present. The host will start processing from location 0 of the indirect attribute memory, after following an implied link from the primary CIS chain in direct attribute memory.
0x1C 0x03 0x03 0x00 0xFF	CISTPL_DEVICE_OC	This tuple allows the device to be operated at 3.3 volts as well as at 5.0 volts.
0x20 0x04 0x79 0x02 0x0B 0x95	CISTPL_MANFID	This tuple specifies the manufacturer ID and product ID codes (0x0279 and 0x950B respectively).
0x21 0x02 0x02 0x02 0x01	CISTPL_FUNCID	This tuple specifies the function of the device, in this case the tuple states the device is a serial port.
0x22 0x04 0x00 0x02 0x0F 0x7F	CISTPL_FUNCE	 This tuple is the function extension tuple, and provides more detailed information about the function of the device, and provides the following information: Serial port includes a 16550 compatible UART. Space, Mark, Odd and Even parity 5, 6, 7, 8 bit chars 1, 1.5 and 2 stop bit operation.
0x15 0x15 0x07 0x01 0x50 0x43 0x20 0x43 0x41 0x52 0x44 0x00	CISTPL_VERS_1	 The Level 1 version / product information tuple provides the host with the following information: The device supports version 7.1 of the PC Card Specification. The Manufacturer String is "PC CARD" The Product String is "GENERIC" The Additional Product Information strings are empty.

0x47 0x45 0x45 0x52 0x49 0x43 0x00 0x00 0x00 0x00 0x00 0xFF 0x1A 0x04 0x00 0x02 0xF8 0x0F	CISTPL_CONFIG	 The CISTPL_CONFIG tuple provides basic configuration information including the following: Base address of the configuration registers (specified as 0xFA) Which configuration registers are present and supported (Configuration Options Register, Configuration Status Register, Pin Replacement Register, and Socket and Copy Register are supported). Index of the last Configuration Table Entry (set to 0x02).
0x1B 0x0D 0xC1 0x41 0x99 0x01 0xB5 0x1E 0xA0 0x40 0x40 0x0F 0xB0 0xFF 0xFF 0xFF 0x07	CISTPL_CFTABLE_ENTRY	 This tuple specifies one particular configuration that the device can be used in. Each configuration has an index number, which is used by the host to select it. This configuration has the following properties: Index is 0x01 READY signal is active, and configuration is for I/O and Memory mode. Nominal Vcc is set to be 3.30 volts. Requests 16 bytes of I/O space. Level interrupts, interrupt sharing are supported. Any interrupt (IRQ0-15) can be used. Maximum number of identical cards is set to 8.
0x1B 0x04 0x02 0x01 0x01 0x55 0xFF	CISTPL_CFTABLE_ENTRY	This configuration is based on the previous configuration, except that it requests Vcc to be 5.0 volts.

Table 18: Card Information Structure Values (Local Bus Mode)

5.6.2 Normal Mode

Value (Hex)	Tuple Name	Description
Direct Att	ribute	
0x01 0x03 0x00	CISTPL_DEVICE	CIS should start with a CISTPL_DEVICE tuple. (Allows operation at 5.0 volts)
0x00 0xFF		

0,10		The CIRTRE DEVICE OC tuple allows anotation at 2.2 wells
0x1C	CISTPL_DEVICE_OC	The CISTPL_DEVICE_OC tuple allows operation at 3.3 volts.

Table 19: Card Information Structure Values (Normal Mode)

6 INTERNAL 950 UART

The internal UART within the OXCF950 is based on the 16C950 rev B, and is henceforth referred to as the 950 core. Some modes of the 16C950 rev B hat are configured by pin options such as Extended-550 mode are not available in this embedded core.

6.1 Mode Selection

The 950 core is software compatible with the 16C450, 16C550, 16C654 and 16C750 UARTs. The operation of the 950 depends on a number of mode ættings. These modes are referred to throughout this data sheet. The FIFO depth and compatibility modes are tabulated below:

UART Mode	FIFO size	FCR[0]	Enhanced mode (EFR[4]=1)	FCR[5] (guarded with LCR[7] = 1)
450	1	0	Х	Х
550	16	1	0	0
650	128	1	1	Х
750	128	1	0	1
950*	128	1	1	Х

Table 20: UART Mode Configuration

* Note that 950 mode configuration is identical to 650 configuration

6.1.1 450 Mode

After a hardware reset bit 0 of the FIFO Control Register ('FCR') is cleared, hence the 950 is compatible with the 16C450. The transmitter and receiver FIFOs (referred to as the 'Transmit Holding Register' and 'Receiver Holding Register' respectively) have a depth of one. This is referred to as 'Byte mode'. When FCR[0] is cleared, all other mode selection parameters are ignored.

6.1.2 550 Mode

After a hardware reset, writing a 1 to FCR[0] will increase the FIFO size to 16, providing compatibility with 16C550 devices.

6.1.3 750 Mode

Writing a 1 to FCR[0] will increase the FIFO size to 16. In a similar fashion to 16C750, the FIFO size can be further increased to 128 by writing a 1 to FCR[5]. Note that access to FCR[5] is protected by LCR[7]. I.e., to set FCR[5], software should first set LCR[7] to temporarily remove the guard. Once FCR[5] is set, the software should clear LCR[7] for normal operation.

The 16C750 additional features over the 16C550 are available as long as the UART is not put into Enhanced mode (i.e. EFR[4] should be '0'). These features are:

- 1. Deeper FIFOs
- 2. Automatic RTS/CTS out-of-band flow control
- 3. Sleep mode

6.1.4 650 Mode

The 950 is compatible with the 16C650 when EFR[4] is set, i.e. the device is in Enhanced mode. As 650 software drivers usually put the device into Enhanced mode, running 650 drivers on the 950 will result in 650 compatibility with 128 deep FIFOs, as long as FCR[0] is set. Note that the 650 emulation mode of the 950 provides 128 byte deep FIFOs whereas the standard 16C650 has only 32 byte FIFOs.

650 mode has the same enhancements as the 16C750 over the 16C550, but these are enabled using different registers.

There are also additional enhancements over those of the 16C750 in this mode, these are:

- 1. Automatic in-band flow control
- 2. Special character detection
- 3. Infra-red "IrDA-format" transmit and receive mode
- 4. Transmit trigger levels
- 5. Optional clock prescaler

6.1.5 950 Mode

The additional features offered in 950 mode generally only apply when the UART is in Enhanced mode (EFR[4]='1'). Provided FCR[0] is set, in Enhanced mode the FIFO size is 128.

Note that 950 mode configuration is identical to that of 650 mode, however additional 950 specific features are

enabled using the Additional Control Register 'ACR' (see section 6.11.3). In addition to larger FIFOs and higher baud rates, the enhancements of the 950 over the 16C654 are:

- Selectable arbitrary trigger levels for the receiver and transmitter FIFO interrupts
- Improved automatic flow control using selectable arbitrary thresholds
- DSR#/DTR# automatic flow control
- Transmitter and receiver can be optionally disabled
- Software reset of device
- Readable FIFO fill levels
- Optional generation of an RS-485 buffer enable signal
- Four-byte device identification (0x16C95006)
- Readable status for automatic in-band and outofband flow control
- External 1x clock modes (see section 6.10.4)
- Flexible "M N/8" clock prescaler (see section 6.10.2)
- Programmable sample clock to allow data rates up to 15 Mbps (see section 6.10.3) at 5V
- 9-bit data mode

The 950 trigger levels are enabled when ACR[5] is set (bits 4 to 7 of FCR are ignored). Then arbitrary trigger levels can be defined in RTL, TTL, FCL and FCH registers (see section 6.11). The Additional Status Register ('ASR') offers flow control status for the local and remote transmitters. FIFO levels are readable using RFL and TFL registers.

The UART has a flexible prescaler capable of dividing the system clock by any value between 1 and 31.875 in steps of 0.125. It divides the system clock by an arbitrary value in

"M N/8" format, where M and N are 5 and 3bit binary numbers programmed in CPR[7:3] and CPR[2:0] respectively. This arrangement offers a great deal of flexibility when choosing an input clock frequency to synthesize arbitrary baud rates. The default division value is 4 to provide backward compatibility with 16C650 devices.

The user may apply an external 1x (or Nx) clock for the transmitter and receiver to the RI# and DSR# pin respectively. The transmitter clock may be asserted on the DTR# pin. The external clock options are selected through the CKS register (offset 0x02 of ICR).

It is also possible to define the over-sampling rate used by the transmitter and receiver clocks. The 16C450/16C550 and compatible devices employ 16 times over-sampling, i.e. There are 16 clock cycles per bit. However, the 950 can employ any over-sampling rate from 4 to 16 by programming the TCR register. This allows the data rates to be increased to 460.8 Kbps using a 1.8432MHz clock, or 15 Mbps using a 60 MHz clock (at 5V). The default value after a reset for this register is 0x00, which corresponds to a 16 cycle sampling clock. Writing 0x01, 0x02 or 0x03 will also result in a 16 cycle sampling clock. To program the value to any value from 4 to 15 it is necessary to write this value into TCR i.e. to set the device to a 13 cycle sampling clock it would be necessary to write 0x0D to TCR. For further information see sections 6.10.3.

The 950 also offers 9bit data frames for multi-drop industrial applications.

OXCF950 DATA SHEET V1.1

6.2 Register Description Tables

The three address lines select the various registers in the UART. Since there are more than 8 registers, selection of the registers is also dependent on the state of the Line Control Register 'LCR' and Additional Control Register 'ACR':

- 1. LCR[7]=1 enables the divider latch registers DLL and DLM.
- LCR specifies the data format used for both transmitter and receiver. Writing 0xBF (an unused format) to LCR enables
 access to the 650 compatible register set. Writing this value will set LCR[7] but leaves LCR[6:0] unchanged. Therefore, the
 data format of the transmitter and receiver data is not affected. Write the desired LCR value to exit from this selection.
- 3. ACR[7]=1 enables access to the 950 specific registers.
- 4. ACR[6]=1 enables access to the Indexed Control Register set (ICR) registers as described on page 27.

Table 24: Indexed Control Register Set

Note 10: The SPR offset column indicates the value that must be written into SPR prior to reading / writing any of the indexed control registers via ICR. Offset values not listed in the table are reserved for future use and must not be used.

To read or write to any of the Indexed Control Registers use the following procedure.

Writing to ICR registers:

Ensure that the last value written to LCR was not 0xBF (reserved for 650 compatible register access value). Write the desired offset to SPR (address 111₂). Write the desired value to ICR (address 101₂).

Reading from ICR registers:

Ensure that the last value written to LCR was not 0xBF (see above). Write 0x00 offset to SPR to select ACR. Set bit 6 of ACR (ICR read enable) by writing x1xxxxx2 to address 1012 Ensure that other bits in ACR are not changed. (Software drivers should keep a copy of the contents of the ACR elsewhere since reading ICR involves overwriting ACR!) Write the desired offset to SPR (address 1112). Read the desired value from ICR (address 1012). Write 0x00 offset to SPR to select ACR.

Clear bit 6 of ACR bye writing x0xxxxx2 to ICR, thus enabling access to standard registers again.

6.3 Reset Configuration

6.3.1 Host Reset

After a hardware reset or soft reset (bit 7 of COR register), all writable registers are reset to 0x00, with the following exceptions:

- 1. DLL which is reset to 0x01.
- 2. CPR is reset to 0x20.

The state of read-only registers following a hardware reset is as follows:

RHR[7:0]: Indeterminate RFL[6:0]: 0000002 TFL[6:0]: 0000002 LSR[7:0]: 0x60 signifying that both the transmitter and the transmitter FIFO are empty MSR[3:0]: 00002 MSR[7:4]: Dependent on modem input lines DCD, RI, DSR and CTS respectively ISR[7:0]: 0x01, i.e. no interrupts are pending ASR[7:0]: 1xx000002 RFC[7:0]: 00000002 GDS[7:0]: 000000012

6.4 Transmitter & Receiver FIFOs

Both the transmitter and receiver have associated holding registers (FIFOs), referred to as the transmitter holding register (THR) and receiver holding register (RHR) respectively.

In normal operation, when the transmitter finishes transmitting a byte it will remove the next data from the top of the THR and proceed to transmit it. If the THR is empty, it will wait until data is written into it. If THR is empty and the last character being transmitted has been completed (i.e. the transmitter shift register is empty) the transmitter is said to be idle. Similarly, when the receiver finishes receiving a byte, it will transfer it to the bottom of the RHR. If the RHR is full, an overrun condition will occur (see section 6.5.3).

DMS[7:0]: 000000102 CKA[7:0]: 00000002

The reset state of output signals for are tabulated below:

Signal	Reset state
SOUT	Inactive High
RTS#	Inactive High
DTR#	Inactive High

Table 25: Output Signal Reset State

6.3.2 Software Reset

An additional feature available in the 950 core is software resetting of the serial channel. The software reset is available using the CSR register. Software reset has the same effect as a hardware reset except it does not reset the clock source selections (i.e. CKS register and CKA register). To reset the UART write 0x00 to the Channel Software Reset register 'CSR'.

Data is written into the bottom of the THR queue and read from the top of the RHR queue completely asynchronously to the operation of the transmitter and receiver.

The size of the FIFOs is dependent on the setting of the FCR register. When in Byte mode, these FIFOs only accept one byte at a time before indicating that they are full; this is compatible with the 16C450. When in a FIFO mode, the size of the FIFOs is either 16 (compatible with the 16C550) or 128.

Data written to the THR when it is full is lost. Data read from the RHR when it is empty is invalid. The empty or full status of the FIFOs are indicated in the Line Status

Register 'LSR' (see section 6.5.3). Interrupts can be generated or DMA signals can be used to transfer data to/from the FIFOs. The number of items in each FIFO may also be read back from the transmitter FIFO level (TFL) and receiver FIFO level (RFL) registers (see section 6.11.2).

6.4.1 FIFO Control Register 'FCR'

FCR[0]: Enable FIFO mode

logic $0 \Rightarrow$ Byte mode. logic $1 \Rightarrow$ FIFO mode.

This bit should be enabled before setting the FIFO trigger levels.

FCR[1]: Flush RHR

 $\begin{array}{rl} \mbox{logic 0} \Rightarrow & \mbox{No change.} \\ \mbox{logic 1} \Rightarrow & \mbox{Flushes the contents of the RHR} \end{array}$

This is only operative when already in a FIFO mode. The RHR is automatically flushed whenever changing between Byte mode and a FIFO mode. This bit will return to zero after clearing the FIFOs.

FCR[2]: Flush THR

logic $0 \Rightarrow$ No change.

logic 1 \Rightarrow Flushes the contents of the THR, in the same manner as FCR[1] does for the RHR.

DMA Transfer Signalling:

FCR[3]: DMA signalling mode / Tx trigger level enable

logic $0 \Rightarrow DMA \mod '0'$.

logic 1 \Rightarrow DMA mode '1'.

DMA signals are not bonded out in the OXCF950, so this control only affects the transmitter trigger level in DMA mode 0.

FCR[5:4]: THR trigger level

Generally in 450, 550, extended 550 and 950 modes these bits are unused (see section 6.1 for mode definition). In 650 mode they define the transmitter interrupt trigger levels and in 750 mode FCR[5] increases the FIFO size.

450, 550 and extended 550 modes:

The transmitter interrupt trigger levels are set to 1 and FCR[5:4] are ignored.

650 mode:

In 650 mode the transmitter interrupt trigger levels are set to the following values:

FCR[5:4]	Transmit Interrupt Trigger level
00	16
01	32
10	64

OXCF950 DATA SHEET V1.1

Table 26: Transmit Interrupt Trigger Levels

These levels only apply when in Enhanced mode and in DMA mode 1 (FCR[3] = 1), otherwise the trigger level is set to 1. A transmitter empty interrupt will be generated (if enabled) if the TFL falls below the trigger level.

750 Mode:

In 750 compatible non-Enhanced (EFR[4]=0) mode, transmitter trigger level is set to 1, FCR[4] is unused and FCR[5] defines the FIFO depth as follows:

FCR[5]=0 Transmitter and receiver FIFO size is 16 bytes. FCR[5]=1 Transmitter and receiver FIFO size is 128 bytes.

In non-Enhanced mode FCR[5] is only writable when LCR[7] is set. Note that in Enhanced mode, the FIFO size is also increased to 128 bytes when FCR[0] is set.

950 mode:

Setting ACR[5]=1 enables arbitrary transmitter trigger level setting using the TTL register (see section 6.11.4), hence FCR[5:4] are ignored.

FCR[7:6]: RHR trigger level

In 550, extended 550, 650 and 750 modes, the receiver FIFO trigger levels are defined using FCR[7:6]. The interrupt trigger level and upper flow control trigger level where appropriate are defined by L2 in the table below. L1 defines the lower flow control trigger level where applicable. Separate upper and lower flow control trigger levels introduce a hysteresis element in in-band and out of band flow control (see section 6.9).

FCR	Mode					
[7:6]	650 FIFO Size 128			750 Size 128	550 FIFO Size 16	
	L1	L2	L1	L2	L1	L2
00	1	16	1	1	n/a	1
01	16	32	1	32	n/a	4
10	32	112	1	64	n/a	8
11	112	120	1	112	n/a	14

Table 27: Receiver Trigger Levels

In Byte mode (450 mode) the trigger levels are all set to 1.

In all cases, a receiver data interrupt will be generated (if enabled) if the Receiver FIFO Level ('RFL') reaches the upper trigger level L2.

950 Mode:

When 950 trigger levels are enabled (ACR[5]=1), more flexible trigger levels can be set by writing to the TTL, RTL, FCL and FCH (see section 6.11) hence ignoring FCR[7:6].

6.5 Line Control & Status

6.5.1 False Start Bit Detection

On the falling edge of a start bit, the receiver will wait for 1/2 bit and re-synchronise the receiver's sampling clock onto the centre of the start bit. The start bit is valid if the SIN line is still low at this mid-bit sample and the receiver will proceed to read in a data character. Verifying the start bit prevents the receiver from assembling a false data character due to a low going noise spike on the SIN input.

Once the first stop bit has been sampled, the received data is transferred to the RHR and the receiver will then wait for a low transition on SIN signifying the next start bit.

The receiver will continue receiving data even if the RHR is full or the receiver has been disabled (see section 6.11.3) in order to maintain framing synchronisation. The only difference is that the received data does not get transferred to the RHR.

6.5.2 Line Control Register 'LCR'

The LCR specifies the data format that is common to both transmitter and receiver. Writing 0xBF to LCR enables access to the EFR, XON1, XOFF1, XON2 and XOFF2, DLL and DLM registers. This value (0xBF) corresponds to an unused data format. Writing the value 0xBF to LCR will set LCR[7] but leaves LCR[6:0] unchanged. Therefore, the data format of the transmitter and receiver data is not affected. Write the desired LCR value to exit from this selection.

LCR[1:0]: Data length

LCR[1:0] Determines the data length of serial characters. Note however, that these values are ignored in 9-bit data framing mode, i.e. when NMR[0] is set.

LCR[1:0]	Data length
00	5 bits
01	6 bits
10	7 bits
11	8 bits

Table 28: LCR Data Length Configuration

LCR[2]: Number of stop bits

LCR[2] defines the number of stop bits per serial character.

LCR[2]	Data length	No. stop bits
0	5,6,7,8	1
1	5	1.5
1	6,7,8	2

Table 29: LCR Stop Bit Number Configuration

LCR[5:3]: Parity type

The selected parity type will be generated during transmission and checked by the receiver, which may produce a parity error as a result. In 9-bit mode parity is disabled and LCR[5:3] is ignored.

LCR[5:3]	Parity type
xx0	No parity bit
001	Odd parity bit
011	Even parity bit
101	Parity bit forced to 1
111	Parity bit forced to 0

Table 30: LCR Parity Configuration

LCR[6]: Transmission break

logic $0 \Rightarrow$ Break transmission disabled.

logic 1 \Rightarrow Forces the transmitter data output SOUT low to alert the communication terminal, or send zeros in IrDA mode.

It is the responsibility of the software driver to ensure that the break duration is longer than the character period for it to be recognised remotely as a break rather than data.

LCR[7]: Divisor latch enable

6.5.3 Line Status Register 'LSR'

This register provides the status of data transfer to CPU.

LSR[0]: RHR data available

- logic $0 \Rightarrow$ RHR is empty: no data available
- logic 1 \Rightarrow RHR is not empty: data is available to be read.

LSR[1]: RHR overrun error

- logic $0 \Rightarrow$ No overrun error.
- logic 1 ⇒ Data was received when the RHR was full. An overrun error has occurred. The error is flagged when the data would normally have been transferred to the RHR.

LSR[2]: Received data parity error

- logic 0 \Rightarrow No parity error in normal mode or 9th bit of received data is '0' in 9-bit mode.
- logic 1 ⇒ Data has been received that did not have correct parity in normal mode or 9^h bit of received data is '1 ' in 9-bit mode.

The flag will be set when the data item in error is at the top of the RHR and cleared following a read of the LSR. In 9-

bit mode LSR[2] is no longer a flag and corresponds to the 9th bit of the received data in RHR.

LSR[3]: Received data framing error

logic $0 \Rightarrow$ No framing error.

This status bit is set and cleared in the same manner as LSR[2]. When a framing error occurs, the UART will try to re-synchronise by assuming that the error was due to sampling the start bit of the next data item.

LSR[4]: Received break error

logic $0 \Rightarrow$ No receiver break error.

logic 1 \Rightarrow The receiver received a break.

A break condition occurs when the SIN line goes low (normally signifying a start bit) and stays low throughout the start, data, parity and first stop bit. (Note that the SIN line is sampled at the bit rate). One zero character with associated break flag set will be transferred to the RHR and the receiver will then wait until the SIN line returns high. The LSR[4] break flag will be set when this data item gets to the top of the RHR and it is cleared following a read of the LSR.

OXCF950 DATA SHEET V1.1

LSR[5]: THR empty

- logic $0 \Rightarrow$ Transmitter FIFO (THR) is not empty.
- logic 1 \Rightarrow Transmitter FIFO (THR) is empty.

LSR[6]: Transmitter and THR empty

- logic $0 \Rightarrow$ The transmitter is not idle
- logic 1 ⇒ THR is empty and the transmitter has completed the character in shift register and is in idle mode. (I.e. set whenever the transmitter shift register and the THR are both empty.)

LSR[7]: Receiver data error

- $\begin{array}{rl} \mbox{logic 0} \Rightarrow & \mbox{Either there are no receiver data errors in the} \\ & \mbox{FIFO or it was cleared by an earlier read of} \\ & \mbox{LSR.} \end{array}$
- logic 1 \Rightarrow At least one parity error, framing error or break indication in the FIFO.

In 450 mode LSR[7] is permanently cleared, otherwise this bit will be set when an erroneous character is transferred from the receiver to the RHR. It is cleared when the LSR is read. Note that in 16C550 this bit is only cleared when all of the erroneous data are removed from the FIFO. In 9-bit data framing mode parity is permanently disabled, so this bit is not affected by LSR[2].

6.6 Interrupts & Sleep Mode

The serial interrupt on the OXCF950 is routed through to the OXCF950 interrupt control, regardless of MCR[3].

6.6.1 Interrupt Enable Register 'IER'

Serial channel interrupts are enabled using the Interrupt Enable Register ('IER').

IER[0]: Receiver data available interrupt mask

logic $0 \Rightarrow$ Disable the receiver ready interrupt.

logic 1 \Rightarrow Enable the receiver ready interrupt.

IER[1]: Transmitter empty interrupt mask

logic 0 \Rightarrow Disable the transmitter empty interrupt. logic 1 \Rightarrow Enable the transmitter empty interrupt.

IER[2]: Receiver status interrupt

Normal mode:

logic $0 \Rightarrow$ Disable the receiver status interrupt.

logic 1 \Rightarrow Enable the receiver status interrupt.

9-bit data mode:

- $logic 0 \Rightarrow$ Disable receiver status and address bit interrupt.
- $logic 1 \Rightarrow$ Enable receiver status and address bit interrupt.

In 9bit mode (i.e. when NMR[0] is set) reception of a character with the address-bit (9th bit) set can generate a level 1 interrupt if IER[2] is set.

IER[3]: Modem status interrupt mask

- logic $0 \Rightarrow$ Disable the modem status interrupt.
- logic 1 \Rightarrow Enable the modem status interrupt.

IER[4]: Sleep mode

- logic $0 \Rightarrow$ Disable sleep mode.
- $\begin{array}{rl} \text{logic 1} \Rightarrow & \text{Enable sleep mode whereby the internal clock} \\ \text{of the channel is switched off.} \end{array}$

Sleep mode is described in section 6.6.4.

IER[5]: Special character interrupt mask or alternate sleep mode

9-bit data framing mode:

- $\mbox{logic 0} \Rightarrow \quad \mbox{Disable the special character receive interrupt}.$
- logic 1 \Rightarrow Enable the special character receive interrupt.

In 9bit data mode, The receiver can detect up to four special characters programmed in Special Character 1 to 4. When IER[5] is set, a level 5 interrupt is asserted when a match is detected.

650/950 modes (non-9-bit data framing):

logic $0 \Rightarrow$ Disable the special character receive interrupt. logic $1 \Rightarrow$ Enable the special character receive interrupt.

In 16C650 compatible mode when the device is in Enhanced mode (EFR[4]=1), this bit enables the detection of special characters. It enables both the detection of XOFF characters (when in-band flow control is enabled via EFR[3:0]) and the detection of the XOFF2 special character (when enabled via EFR[5]).

750 mode (non-9-bit data framing):

- logic $0 \Rightarrow$ Disable alternate sleep mode.
- logic 1 \Rightarrow Enable alternate sleep mode whereby the internal clock of the channel is switched off.

In 16C750 compatible mode (i.e. non-Enhanced mode), this bit is used an alternate sleep mode and has the same effectas IER[4]. (See section 6.6.4)

IER[6]: RTS interrupt mask

This enable is only operative in Enhanced mode (EFR[4]=1). In non-Enhanced mode, RTS interrupt is permanently enabled.

IER[7]: CTS interrupt mask

This enable is only operative in Enhanced mode (EFR[4]=1). In non-Enhanced mode, CTS interrupt is permanently enabled.

6.6.2 Interrupt Status Register 'ISR'

The source of the highest priority interrupt pending is indicated by the contents of the Interrupt Status Register 'ISR'. There are nine sources of interrupt at six levels of priority (1 is the highest) as tabulated below:

Level	Interrupt source	ISR[5:0] see note 3
-	No interrupt pending ¹	000001
1	Receiver status error or Address-bit detected in 9-bit mode	000110
2a	Receiver data available	000100
2b	Receiver time-out	001100
3	Transmitter THR empty	000010
4	Modem status change	000000
5 ²	In-band flow control XOFF or Special character (XOFF2) or Special character 1, 2, 3 or 4 or bit 9 set in 9-bit mode	010000
6 ²	CTS or RTS change of state	100000

 Table 31: Interrupt Status Identification Codes

Note1: ISR[0] indicates whether any interrupts are pending. Note2: Interrupts of priority levels 5 and 6 cannot occur unless the UART is in Enhanced mode.

Note3: ISR[5] is only used in 650 & 950 modes. In 750 mode, it is '0' when FIFO size is 16 and '1' when FIFO size is 128. In all other modes it is permanently set to '0'.

6.6.3 Interrupt Description

Level 1:

Receiver status error interrupt (ISR[5:0]='000110'):

Normal (non-9-bit) mode:

This interrupt is active whenever any of LSR[1], LSR[2], LSR[3] or LSR[4] are set. These flags are cleared following a read of the LSR. This interrupt is masked with IER[2].

9-bit mode:

This interrupt is active whenever any of LSR[1], LSR[2], LSR[3] or LSR[4] are set. The receiver error interrupt due to LSR[1], LSR[3] and LSR[4] is masked with IER[3]. The 'address-bit' received interrupt is masked with NMR[1]. The software driver can differentiate between receiver status error and received address-bit (9th data bit) interrupt by examining LSR[1] and LSR[7]. In 9-bit mode LSR[7] is only set when LSR[3] or LSR[4] is set and it is not affected by LSR[2] (i.e. 9th data bit).

Level 2a:

Receiver data available interrupt (ISR[5:0]='000100'):

OXCF950 DATA SHEET V1.1

This interrupt is active whenever the receiver FIFO level is above the interrupt trigger level.

Level 2b:

Receiver time-out interrupt (ISR[5:0]='001100'):

A receiver time-out event, which may cause an interrupt, will occur when all of the following conditions are true:

- The UART is in a FIFO mode
- There is data in the RHR.
- There has been no read of the RHR for a period of time greater than the time-out period.
- There has been no new data received and written into the RHR for a period of time greater than the time-out period. The time-out period is four times the character period (including start and stop bits) measured from the centre of the first stop bit of the last data item received.

Reading the first data item in RHR clears this interrupt.

Level 3:

Transmitter empty interrupt (ISR[5:0]='000010'):

This interrupt is set when the transmit FIFO evel falls below the trigger level. It is cleared on an ISR read of a level 3 interrupt or by writing more data to the THR so that the trigger level is exceeded. Note that when 950 mode trigger levels are enabled (ACR[5]=1) and the transmitter trigger level of zero is selected (TTL=0x00), a transmitter empty interrupt will only be asserted when both the transmitter FIFO and transmitter shift register are empty and the SOUT line has returned to idle marking state.

Level 4:

Modem change interrupt (ISR[5:0]='000000'):

This interrupt is set by a modem change flag (MSR[0], MSR[1], MSR[2] or MSR[3]) becoming active due to changes in the input modem lines. This interrupt is cleared following a read of the MSR.

Level 5:

Receiver in-band flow control (XOFF) detect interrupt, Receiver special character (XOFF2) detect interrupt, Receiver special character 1, 2, 3 or 4 interrupt or 9th Bit set interrupt in 9-bit mode (ISR[5:0]='010000'): A level 5 interrupt can only occur in Enhanced-mode when any of the following conditions are met:

- A valid XOFF character is received while in-band flow control is enabled.
- A received character matches XOFF2 while special character detection is enabled.
- A received character matches special character 1, 2, 3 or 4 in 9-bit mode (see secton 6.11.9).

It is cleared on an ISR read of a level 5 interrupt.

Level 6:

CTS or RTS changed interrupt (ISR[5:0]='100000'):

This interrupt is set whenever either of the CTS# or RTS# pins changes state from low to high. It is cleared on an ISR read of a level 6 interrupt.

6.6.4 Sleep Mode

For a channel to go into sleep mode, all of the following conditions must be met:

- Sleep mode enabled (IER[4]=1 in 650/950 modes, or IER[5]=1 in 750 mode):
- The transmitter is idle, i.e. the transmitter shift register and FIFO are both empty.
- SIN is high.

6.7 Modem Interface

6.7.1 Modem Control Register 'MCR'

MCR[0]: DTR

logic 0 \Rightarrow Force DTR# output to inactive (high).

logic 1 \Rightarrow Force DTR# output to active (low).

Note that DTR# can be used for automatic outof band flow control when enabled using ACR[4:3] (see section 6.11.3).

MCR[1]: RTS

 $\begin{array}{rcl} \text{logic } 0 \Rightarrow & \text{Force RTS\# output to inactive (high).} \\ \text{logic } 1 \Rightarrow & \text{Force RTS\# output to active (low).} \end{array}$

Note that RTS# can be used for automatic outof band flow control when enabled using EFR[6] (see section 6.9.4).

MCR[2]: OUT1

- logic 0 \Rightarrow Force OUT1# output low when loopback mode is disabled.
- logic 1 \Rightarrow Force OUT1# output high.

OUT1# is not bonded out in the OXCF950, but is internally used for loopback testing

MCR[3]: OUT2

- logic 1 \Rightarrow Force OUT2# output high.

OUT2# is not bonded out in the OXCF950, but is internally used for loopback testing

MCR[4]: Loopback mode

logic $0 \Rightarrow$ Normal operating mode.

- The receiver is idle.
- The receiver FIFO is empty (LSR[0]=0).
- The UART is not in loopback mode (MCR[4]=0).
- Changes on modem input lines have been acknowledged (i.e. MSR[3:0]=0000).
- No interrupts are pending.

A read of IER[4] (or IER[5] if a 1 was written to that bit instead) shows whether the power-down request was successful. The UART will fully retain its programmed state whilst in power-down mode.

The channel will automatically exit power-down mode when any of the conditions 1 to 7 becomes false. It may be woken manually by clearing IER[4] (or IER[5] if the alternate sleep mode is enabled).

Sleep mode operation is not available in IrDA mode.

logic 1 \Rightarrow Enable local loop-back mode (diagnostics).

In local loop-back mode, the transmitter output (SOUT) and the modem outputs (DTR#, RTS#) are set in-active (high), and the receiver inputs SIN, CTS#, DSR#, DCD#, and RI# are all disabled. Internally the transmitter output is connected to the receiver input and DTR#, RTS#, OUT1# and OUT2# are connected to modem status inputs DSR#, CTS#, RI# and DCD# respectively.

In this mode, the receiver and transmitter interrupts are fully operational. The modem control interrupts are also operational, but the interrupt sources are now the lower four bits of the Modem Control Register instead of the four modem status inputs. The interrupts are still controlled by the IER.

MCR[5]: Enable XON-Any in Enhanced mode or enable out-of-band flow control in non-Enhanced mode

 $650/950 \mod es$ (Enhanced mode): logic 0 \implies XON-Any is disabled. logic 1 \implies XON-Any is enabled.

In enhanced mode (EFR[4]=1), this bit enables the Xon-Any operation. When Xon-Any is enabled, any received data will be accepted as a valid XON (see in-band flow control, section 6.9.3).

750 mode (Non-Enhanced mode): logic $0 \Rightarrow$ CTS/RTS flow control disabled. logic $1 \Rightarrow$ CTS/RTS flow control enabled.

OXCF950 DATA SHEET V1.1

In non-enhanced mode, this bit enables the CTS/RTS outof-band flow control.

MCR[6]: IrDA mode

- $\begin{array}{rl} \text{logic 0} \Rightarrow & \text{Standard serial receiver and transmitter data} \\ & \text{format.} \end{array}$
- $\begin{array}{rl} \text{logic 1} \Rightarrow & \text{Data will be transmitted and received in IrDA} \\ & \text{format.} \end{array}$

This function is only available in Enhanced mode. It requires a 16x clock to function correctly.

MCR[7]: Baud rate prescaler select

- logic 0 \Rightarrow Normal (divide by 1) baud rate generator prescaler selected.
- logic 1 \Rightarrow Divide-by-"M N/8" baud rate generator prescaler selected.

Where M & N are programmed in CPR (ICR offset 0x01). After a hardware reset, CPR defaults to 0x20 (divide-by-4) and MCR[7] is reset to '0'. User writes to this flag will only take effect in enhanced mode. See section 6.9.1.

6.7.2 Modem Status Register 'MSR'

MSR[0]: Delta CTS#

Indicates that the CTS# input has changed since the last time the MSR was read.

MSR[1]: Delta DSR#

6.8 Other Standard Registers

6.8.1 Divisor Latch Registers 'DLL & DLM'

The divisor latch registers are used to program the baud rate divisor. This is a value between 1 and 65535 by which the input clock is divided by in order to generate serial baud rates. After a hardware reset, the baud rate used by the transmitter and receiver is given by:

$$Baudrate = \frac{InputClock}{16 * Divisor}$$

Where divisor is given by DLL + ($256 \times DLM$). More flexible baud rate generation options are also available. See section 6.10 for full details.

6.9 Automatic Flow Control

Automatic in-band flow control, automatic outofband flow control and special character detection features can be used when in Enhanced mode and are software compatible with the 16C654. Alternatively, 16C750 compatible automatic outofband flow control can be enabled when in non-Enhanced mode. In 950 mode, in-band and outof-

Indicates that the DSR# input has changed since the last time the MSR was read.

MSR[2]: Trailing edge RI#

Indicates that the RI# input has changed from low to high since the last time the MSR was read.

MSR[3]: Delta DCD#

Indicates that the DCD# input has changed since the last time the MSR was read.

MSR[4]: CTS

This bit is the complement of the CTS# input. It is equivalent to RTS (MCR[1]) during internal loop-back mode.

MSR[5]: DSR

This bit is the complement of the DSR# input. It is equivalent to DTR (MCR[0]) during internal loop-back mode.

MSR[6]: RI

This bit is the complement of the RI# input. In internal loopback mode it is equivalent to the internal OUT1.

MSR[7]: DCD

This bit is the complement of the DCD# input. In internal loop-back mode it is equivalent to the internal OUT2.

6.8.2 Scratch Pad Register 'SPR'

The scratch pad register does not affect operation of the rest of the UART in any way and can be used for temporary data storage. The register may also be used to define an offset value to access the registers in the Indexed Control Register set. For more information on Indexed Control registers see Table 24 and section 6.11.

band flow controls are compatible with 16C654, with the addition of fully programmable flow control thresholds.

6.9.1 Enhanced Features Register 'EFR'

Writing 0xBF to LCR enables access to the EFR and other Enhanced mode registers. This value corresponds to an

OXCF950 DATA SHEET V1.1

unused data format. Writing 0xBF to LCR will set LCR[7] but leaves LCR[6:0] unchanged. Therefore, the data format of the transmitter and receiver data is not affected. Write the desired LCR value to exit from this selection.

Note: In-band transmit and receive flow control is disabled in 9-bit mode.

EFR[1:0]: In-band receive flow control mode

When in-band receive flow control is enabled, the UART compares the received data with the programmed XOFF character(s). When this occurs, the UART will disable transmission as soon as any current character transmission is complete. The UART then compares the received data with the programmed XON character(s). When a match occurs, the UART will re-enable transmission (see section 6.11.6).

For automatic in-band flow control, bit 4 of EFR must be set. The combinations of software receive flow control can be selected by programming EFR[1:0] as follows:

- logic $[00] \Rightarrow$ In-band receive flow control is disabled.
- logic [01] ⇒ Single character in-band receive flow control enabled, recognising XON2 as the XON character and XOFF2 as the XOFF character.
- logic [10] ⇒ Single character in-band receive flow control enabled, recognising XON1 as the XON character and XOFF1 and the XOFF character.
- logic [11] ⇒ The behaviour of the receive flow control is dependent on the configuration of EFR[3:2]. single character in-band receive flow control is enabled, accepting both XON1 and XON2 as valid XON characters and both XOFF1 and XOFF2 as valid XOFF characters when EFR[3:2] = "01" or "10". EFR[1:0] should not be set to "11" when EFR[3:2] is either "00".

EFR[3:2]: In-band transmit flow control mode

When in-band transmit flow control is enabled, XON/XOFF character(s) are inserted into the data stream whenever the RFL passes the upper trigger level and falls below the lower trigger level respectively.

For automatic in-band flow control, bit 4 of EFR must be set. The combinations of software tansmit flow control can then be selected by programming EFR[3:2] as follows:

logic $[00] \Rightarrow$ In-band transmit flow control is disabled.

OXCF950 DATA SHEET V1.1

- logic [10] ⇒ Single character in-band transmit flow control enabled, using XON1 as the XON character and XOFF1 as the XOFF character.
- $Logic[11] \Rightarrow$ The value EFR[3:2] = "11" is reserved for future use and should not be used

EFR[4]: Enhanced mode

- logic 0 ⇒ Non-Enhanced mode. Disables IER bits 47, ISR bits 4-5, FCR bits 4-5, MCR bits 5-7 and in-band flow control. Whenever this bit is cleared, the setting of other bits of EFR are ignored.
- logic 1 ⇒ Enhanced mode. Enables the Enhanced Mode functions. These functions include enabling IER bits 4-7, FCR bits 4-5, MCR bits 5-7. For in-band flow control the software driver must set this bit first. If this bit is set, out-of-band flow control is configured with EFR bits 6-7, otherwise out-of-band flow control is compatible with 16C750.

EFR[5]: Enable special character detection

- logic $0 \Rightarrow$ Special character detection is disabled.
- logic 1 ⇒ While in Enhanced mode (EFR[4]=1), the UART compares the incoming receiver data with the XOFF2 value. Upon a correct match, the received data will be transferred to the RHR and a level 5 interrupt (XOFF or special character) will be asserted if level 5 interrupts are enabled (IER[5] set to 1).

EFR[6]: Enable automatic RTS flow control.

- logic $0 \Rightarrow$ RTS flow control is disabled (default).

EFR[7]: Enable automatic CTS flow control.

logic $0 \Rightarrow$ CTS flow control is disabled (default).

logic 1 ⇒ CTS flow control is enabled in Enhanced mode (i.e. EFR[4] = 1), where the data transmission is prevented whenever the CTS# pin is held inactive high. The 650 and 950 software drivers should use this bit to enable CTS flow control. The 750 compatible driver uses MCR[5] to enable CTS flow control.

6.9.2 Special Character Detection

In Enhanced mode (EFR[4]=1), when special character detection is enabled (EFR[5]=1) and the receiver matches received data with XOFF2, the 'received special character' flag ASR[4] will be set and a level 5 interrupt is asserted, (if enabled by IER[5]). This flag will be cleared following a read of ASR. The received status (i.e. parity and framing) of special characters does not have to be valid for these characters to be accepted as valid matches.

6.9.3 Automatic In-band Flow Control

When in-band receive flow control is enabled, the UART will compare the received data with XOFF1 or XOFF2 characters to detect an XOFF condition. When this occurs, the UART will disable transmission as soon as any current character transmission is complete. Status bits ISR[4] and ASR[0] will be set. A level 5 interrupt will occur if enabled by IER[5]. The UART will then compare all received data with XON1 or XON2 characters to detect an XON condition. When this occurs, the UART will re-enable transmission and status bits ISR[4] and ASR[0] will be cleared.

Any valid XON/XOFF characters will not be written into the RHR. An exception to this rule occurs if special character detection is enabled and an XOFF2 character s received that is a valid XOFF. In this instance, the character will be written into the RHR.

The received status (i.e. parity and framing) of XON/XOFF characters does not have to be valid for these characters to be accepted as valid matches.

When the 'XON Any' flag (MCR[5]) is set, any received character is accepted as a valid XON condition and the transmitter will be re-enabled. The received data will be transferred to the RHR.

When in-band transmit flow control is enabled, the RFL will be sampled whenever the transmitter is idle (briefly, between characters, or when the THR is empty) and an XON/XOFF character may be inserted into the data stream

6.10 Baud Rate Generation

6.10.1 General Operation

The UART contains a programmable baud rate generator that is capable of taking any clock input from DC to 60MHz(at 5V) and dividing itby any 16-bit divisor number from 1 to 65535 written into the DLM (MSB) and DLL (LSB) registers. In addition to this, a clock prescaler register is provided which can further divide the clock by values in the range 1.0 to 31.875 in steps of 0.125. Also, a further feature is the Times Clock Register 'TCR' which allows the sampling clock to be set to any value between 4 and 16.

if needed. Initially, remote transmissions are enabled and hence ASR[1] is clear. If ASR[1] is clear and the RFL has passed the upper trigger level (i.e. is above the trigger level), XOFF will be sent and ASR[1] will be set. If ASR[1] is set and the RFL falls below the lower trigger level, XON will be sent and ASR[1] will be cleared.

If transmit flow control is disabled after an XOFF has been sent, an XON will be sent automatically.

6.9.4 Automatic Outof-band Flow Control

Automatic RTS/CTS flow control is selected by different means, depending on whether the UART is in Enhanced or non-Enhanced mode. When in non-Enhanced mode, MCR[5] enables both RTS and CTS flow control. When in Enhanced mode, EFR[6] enables automatic RTS flow control and EFR[7] enables automatic CTS flow control. This allows software compatibility with both 16C650 and 16C750 drivers.

When automatic CTS flow control is enabled and the CTS# input becomes active, the UART will disable transmission as soon as any current character transmission is complete. Transmission is resumed whenever the CTS# input becomes inactive.

When automatic RTS flow control is enabled, the RTS# pin will be forced inactive when the RFL reaches the upper trigger level and will return to active when the RFL falls below the lower trigger level. The automatic RTS# flow control is ANDed with MCR[1] and hence is only operational when MCR[1]=1. This allows the software driver to override the automatic flow control and disable the remote transmitter regardless by setting MCR[1]=0 at any time.

Automatic DTR/DSR flow control behaves in the same manner as RTS/CTS flow control but is enabled by ACR[3:2], regardless of whether or not the UART is in Enhanced mode.

These clock options allow for highly flexible baud rate generation capabilities from almost any input clock frequency (up to 60MHz at 5V). The actual transmitter and receiver baud rate is calculated as follows:

 $BaudRate = \frac{InputClock}{SC*Divisor*prescaler}$

Where:

SC	= Sample clock values defined in TCR[3:0]
Divisor	= DLL + (256 x DLM)
Prescale	r= 1 when MCR[7] = '0' else:
	= M + (N / 8) where:
Μ	= CPR[7:3] (Integer part - 1 to 31)
Ν	= CPR[2:0] (Fractional part - 0.000 to 0.875)

See next section for a discussion of the clock prescaler and times clock register.

After a hardware reset, the prescaler is bypassed (set to 1) and TCR is set to 0x00 (.e. SC = 16). Assuming this default configuration, the following table gives the divisors required to be programmed into the DLL and DLM registers in order to obtain various standard baud rates:

DLM:DLL Divisor Word	Baud Rate (bits per second)
0x0900	50
0x0300	110
0x0180	300
0x00C0	600
0x0060	1,200
0x0030	2,400
0x0018	4,800
0x000C	9,600
0x0006	19,200
0x0004	28,800
0x0003	38,400
0x0002	57,600
0x0001	115,200

Table 32: Standard PC COM Port Baud Rate Divisors (assuming a 1.8432MHz crystal)

6.10.2 Clock Prescaler Register 'CPR'

The CPR register is located at offset 0x01 of the ICR

The prescaler divides the system clock by any value in the range of 1 to "31 7/8" in steps of 1/8. The divisor takes the form "M + N/8", where M is the 5 bit value defined in CPR[7:3] and N is the 3 bit value defined in CPR[2:0].

The prescaler is by-passed and a prescaler value of '1' is selected by default when MCR[7] = 0.

MCR[7] is reset to '0' after a hardware reset but may be overwritten by software. Note however that since access to MCR[7] is restricted to Enhanced mode only, EFR[4] should first be set and then MCR[7] set or cleared as required. OXCF950 DATA SHEET V1.1

If MCR[7] is set by software, the internal clock prescaler is enabled.

Upon a hardware reset, CPR defaults to 0x20 (division-by-4). Compatibility with existing 16C550 baud rate divisors is maintained using a 1.8432MHz clock.

For higher baud rates use a higher frequency clock, e.g. 14.7456MHz, 18.432MHz, 32MHz, 40MHz or 60.0MHz. The flexible prescaler allows system designers to generate popular baud rates using clocks that are not integer multiples of the required rate. When using a non-standard clock frequency, compatibility with existing 16C550 software drivers may be maintained with a minor software patch to program the on-board prescaler to divide the high frequency clock down to 1.8432MHz.

Table 34 on the following page gives the prescaler values required to operate the UARTs at compatible baud rates with various different crystal frequencies. Also given is the maximum available baud rates in TCR = 16 and TCR = 4 modes with CPR = 1.

6.10.3 Times Clock Register 'TCR'

The TCR register is located at offset 0x02 of the ICR

The 16C550 and other compatible devices such as 16C650 and 16C750 use a 16 times (16x) over-sampling channel clock. The 16x over-sampling clock means that the channel clock runs at 16 times the selected serial bit rate. It limits the highest baud rate to 1/16 of the system clock when using a divisor latch value of unity. However, the 950 UART is designed in a manner to enable it to accept other multiplications of the bit rate clock. It can use values from 4x to 16x clock as programmed in the TCR as long as the clock (oscillator) frequency error, stability and jitter are within reasonable parameters. Upon hardware reset the TCR is reset to 0x00 which means that a 16x clock will be used, for compatibility with the 16C550 and compatibles.

The maximum baud-rates available for various system clock frequencies at all of the allowable values of TCR are indicated in Table 35 on the following page. These are the values in bits-per-second (bps) that are obtained if the divisor latch = 0x01 and the Prescaler is set to 1.

The OXCF950 has the facility to operate at baud-rates up to 15 Mbps at 5V.

The table below indicates how the value in the register corresponds to the number of clock cycles per bit. TCR[3:0] is used to program the clock. TCR[7:4] are unused and will return "0000" if read.

TCR[3:0]	Clock cycles per bit
0000 to 0011	16
0100 to 1111	4-15

Table 33: TCR Sample Clock Configuration

The use of TCR does not require the device to be in 650 or 950 mode although only drivers that have been written to take advantage of the 950 mode features will be able to access this register. Writing 0x01 to the TCR will not switch

the device into 1x isochronous mode, this is explained in the following section. (TCR has no effect in isochronous mode). If 0x01, 0x10 or 0x11 is written to TCR the device will operate in 16x mode.

Reading TCR will always return the last value that was written to it irrespective of mode of operation.

Clock Frequency (MHz)	CPR value	Effective crystal frequency	Error from 1.8432MHz (%)	Max. Baud rate with CPR = 1, TCR = 16	Max. Baud rate with CPR = 1, TCR = 4
1.8432	0x08 (1.000)	1.8432	0.00	115,200	460,800
7.3728	0x20(4.000)	1.8432	0.00	460,800	1,843,200
14.7456	0x80 (8.000)	1.8432	0.00	921,600	3,686,400
18.432	0x50 (10.000)	1.8432	0.00	1,152,000	4,608,000
32.000	0x8B(17.375)	1.8417	0.08	2,000,000	8,000,000
33.000	0x8F (17.875)	1.8462	0.16	2,062,500	8,250,000
40.000	0xAE (21.750)	1.8391	0.22	2,500,000	10,000,000
50.000	0xD9 (27.125)	1.8433	0.01	3,125,000	12,500,000
60.000*	0xFF (31.875)	1.8824	2.13	3,750,000	15,000,000

Table 34: Example clock options and their assosiacted maximum baud rates

Sampling	TCR		System Clock (MHz)						
Clock	Value	1.8432	7.372	14.7456	18.432	32	40	50	60
16	0x00	115,200	460,750	921,600	1.152M	2.00M	2.50M	3.125M	3.75M

Table 35: Maximum Baud Rates Available at all 'TCR' Sampling Clock Values

6.10.4 Input Clock Options

A system clock must be applied to XTLI pin on the device. The speed of this clock determines the maximum baud rate at which the device can receive and transmit serial data. This maximu m is equal to one sixteenth of the frequency of the system clock (Increasing to one quarter of this value if TCR=4 is used). The industry standard system clock for PC COM ports is 1.8432 MHz, limiting the maximum baud rate to 115.2 Kbps. The OXCF950 supports system clocks up to 60MHz at 5V or 50 MHz at 3.3V and its flexible baud rate generation hardware means that almost any frequency can be optionally scaled down for compatibility with standard devices.

Designers have the option of using either TTL clock modules or crystal oscillator circuits for system clock input, with minimal additional components. The following two sections describe how each can be connected.

6.10.5 TTL Clock Module

Using a TTL module for the system clock simply requires the module to be supplied with +5v power and GND connections. The clock output can then be connected directly to XTLI. XTLO should be left unconnected.

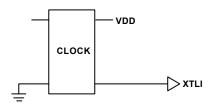

Figure 5: TTL Clock Module Connectivity

6.10.6 External 1x Clock Mode

The transmitter and receiver can accept an external clock applied to the RI# and DSR# pins respectively. The clock options are selected using the clock select register (CKS - see section 6.11.8). The transmitter and receiver may be configured to operate in 1x (Isochronous) mode by setting CKS[7] and CKS[3], respectively. In Isochronous mode, transmitter or receiver will use the 1x clock (usually but not necessarily an external source) where asynchronous framing is maintained using start, parity and stop-bits. However serial transmission and reception is synchronised to the 1x clock. In this mode asynchronous data may be transmitted at baud rates up to 60Mbps. The local 1x clock source can be asserted on the DTR# pin.

6.11 Additional Features

6.11.1 Additional Status Register 'ASR'

ASR[0]: Transmitter disabled

- logic $0 \Rightarrow$ The transmitter is not disabled by in-band flow control.
- logic 1 \Rightarrow The receiver has detected an XOFF, and has disabled the transmitter.

This bit **s** cleared after a hardware reset or channel software reset. The software driver may write a 0 to this bit to re-enable the transmitter if it was disabled by in-band flow control. Writing a 1 to this bit has no effect.

ASR[1]: Remote transmitter disabled

 $\begin{array}{rl} \text{logic 0} \Rightarrow & \text{The remote transmitter is not disabled by inband flow control.} \end{array}$

Note that line drivers need to be capable of transmission at data rates twice the system clock used (as one cycle of the system clock corresponds to 1 bit of serial data). Also note that enabling modem interrupts is illegal in isochronous mode, as the clock signal will cause a continuous change to the modem status (unless masked in MDM register, see section 6.11.10).

6.10.7 Crystal Oscillator Circuit

The OXCF950 may be clocked by a crystal connected to XTLI and XTLO or directly from a clock source connected to the XTLI pin. The circuit required to use the on-chip oscillator is shown opposite.

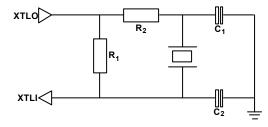

Figure 6: Crystal Oscillator Circuit

Frequency Range (MHz)	C1 (pF)	C2 (pF)	R1 (W)	R2(W)
1.8432 – 8	68	22	220K	470R
8-60	33-68	33 – 68	220K-2M2	470R

Table 36: Component Values

Note: For better stability use a smaller value of R₁. Increase R₁ to reduce power consumption. The total capacitive load (C1 in series with C2) should be that specified by the crystal manufacturer (nominally 16pF)

logic 1 \Rightarrow The transmitter has sent an XOFF character, to disable the remote transmitter. (Cleared when a subsequent XON is sent).

This bit is cleared after a hardware reset or channel software reset. The software driver may write a 0 to this bit to re-enable the remote transmitter (an XON is transmitted). Writing a 1 to this bit has no effect.

Note : The remaining bits (ASR[7:2]) of this register are read only

ASR[2]: RTS

This is the complement of the actual state of the RTS# pin when the device is not in loopback mode. The driver software can determine if the remote transmitter is disabled by RTS# out-of-band flow control by reading this bit. In

OXCF950 DATA SHEET V1.1

loopback mode this bit reflects the flow control status rather than the pin's actual state.

ASR[3]: DTR

This is the complement of the actual state of the DTR# pin when the device is not in loopback mode. The driver software can determine if the remote transmitter is disabled by DTR# out-of-band flow control by reading this bit. In loopback mode this bit reflects the flow control status rather than the pin's actual state.

ASR[4]: Special character detected

logic $0 \Rightarrow$ No special character has been detected.

logic 1 \Rightarrow A special character has been received and is stored in the RHR.

This can be used to determine whether a level 5 interrupt was caused by receiving a special character rather than an XOFF. The flag is cleared following the read of the ASR.

ASR[5]: RESERVED

This bit is unused in the OXCF950 and reads '0'.

ASR[6]: FIFO size

logic $0 \Rightarrow$ FIFOs are 16 deep if FCR[0] = 1. logic 1 \Rightarrow FIFOs are 128 deep if FCR[0] = 1.

Note: If FCR[0] = 0, the FIFOs are 1 deep.

ASR[7]: Transmitter Idle

 $logic 0 \Rightarrow$ Transmitter is transmitting. $logic 1 \Rightarrow$ Transmitter is idle.

This bit reflects the state of the internal transmitter. It is set when both the transmitter FIFO and shift register are empty.

6.11.2 FIFO Fill levels 'TFL & RFL'

The number of characters stored in the THR and RHR can be determined by reading the TFL and RFL registers respectively. As the UART clock is asynchronous with respect to the processor, it is possible for the levels to change during a read of these FIFO levels. It is therefore recommended that the levels are read twice and compared to check that the values obtained are valid. The values should be interpreted as follows:

- The number of characters in the THR is no greater 1 than the value read back from TFL.
- 2 The number of characters in the RHR is no less than the value read back from RFL.

6.11.3 Additional Control Register 'ACR'

The ACR register is located at offset 0x00 of the ICR

ACR[0]: Receiver disable

- logic $0 \Rightarrow$ The receiver is enabled, receiving data and storing it in the RHR.
- logic $1 \Rightarrow$ The receiver is disabled. The receiver continues to operate as normal to maintain the framing synchronisation with the receive data stream but received data is not stored into the RHR. In-band flow control characters continue to be detected and acted upon. Special characters will not be detected.

Changes to this bit will only be recognised following the completion of any data reception pending.

ACR[1]: Transmitter disable

- logic $0 \Rightarrow$ The transmitter is enabled, transmitting any data in the THR.
- The transmitter is disabled. Any data in the logic $1 \Rightarrow$ THR is not transmitted but is held. However, in-band flow control characters may still be transmitted.

Changes to this bit will only be recognised following the completion of any data transmission pending.

ACR[2]: Enable automatic DSR flow control

- logic $0 \Rightarrow$ Normal. The state of the DSR# line does not affect the flow control.
- logic $1 \Rightarrow$ Data transmission is prevented whenever the DSR# pin is held inactive high.

This bit provides another automatic out-of-band flow control facility using the DSR# line.

ACR[4:3]: DTR# line configuration

When bits 4 or 5 of CKS (offset 0x03 of ICR) are set, the transmitter 1x clock or the output of the baud rate generator (Nx clock) are asserted on the DTR# pin, otherwise the DTR# pin is defined as follows:

- logic $[00] \Rightarrow$ DTR# is compatible with 16C450, 16C550, 16C650 and 16C750 (i.e. normal).
- DTR# pin is used for outof-band flow logic [01] \Rightarrow control. It will be forced inactive high if the Receiver FIFO Level ('RFL') reaches the upper flow control threshold. DTR# line will be re-activated when the RFL drops below the lower threshold (see FCL & FCH).
- logic [10] \Rightarrow DTR# pin is configured to drive the active low enable pin of an external RS485 buffer. In this configuration the DTR# pin will be forced low whenever the transmitter is not empty (LSR[6]=0), otherwise DTR# pin is high.

logic [11] ⇒ DTR# pin is configured to drive the active high enable pin of an external RS485 buffer. In this configuration, the DTR# pin will be forced high whenever the transmitter is not empty (LSR[6]=0), otherwise DTR# pin is low.

If the user sets ACR[4], then the DTR# line is controlled by the status of the transmitter empty bit of LCR. When ACR[4] is set, ACR[3] is used to select active high or active low enable signals. In halfduplex systems using RS485 probcol, this facility enables the DTR# line to directly control the enable signal of external 3-state line driver buffers. When the transmitter is empty the DTR# would go inactive once the SOUT line returns to it's idle marking state.

ACR[5]: 950 mode trigger levels enable

ACR[6]: ICR read enable

logic $0 \Rightarrow$ The Line Status Register is readable.

logic 1 \Rightarrow The Indexed Control Registers are readable.

Setting this bit will map the ICR set to the LSR location for reads. During normal operation this bit should be cleared.

ACR[7]: Additional status enable

- logic 0 \Rightarrow Access to the ASR, TFL and RFL registers is disabled.
- logic 1 \Rightarrow Access to the ASR, TFL and RFL registers is enabled.

When ACR[7] is set, the MCR and LCR registers are no longer readable but remain writable, and the TFL and RFL registers replace them in the memory map for read operations. The IER register is replaced by the ASR register for all operations. The software driver may leave this bit set during normal operation, since MCR, LCR and IER do not generally need to be read.

6.11.4 Transmitter Trigger Level 'TTL'

The TTL register is located at offset 0x04 of the ICR

Whenever 950 trigger levels are enabled (ACR[5]=1), bits 4 and 5 of FCR are ignored and an alternative arbitrary transmitter interrupt trigger level can be defined in the TTL register. This 7bit value provides a fully programmable transmitter interrupt trigger facility. In 950 mode, a priority level 3 interrupt occurs indicating that the transmitter buffer requires more characters when the interrupt is not masked (IER[1]=1) and the transmitter FIFO level falls below the value stored in the TTL register. The value 0 (0x00) has a special meaning. In 950 mode when the user writes 0x00 to the TTL register, a level 3 interrupt only occurs when the FIFO and the transmitter shift register are both empty and the SOUT line is in the idle marking state. This feature is particularly useful to report back the empty state of the transmitter after its FIFO has been flushed away.

6.11.5 Receiver Interrupt. Trigger Level 'RTL'

The RTL register is located at offset 0x05 of the ICR

Whenever 950 trigger levels are enabled (ACR[5]=1), bits 6 and 7 of FCR are ignored and an alternative arbitrary receiver interrupt trigger level can be defined in the RTL register. This 7bit value provides a fully programmable receiver interrupt trigger facility as opposed to the limited trigger levels available in 16C650 and 16C750 devices. It enables the system designer to optimise the interrupt performance hence minimising the interrupt overhead.

In 950 mode, a priority level 2 interrupt occurs indicating that the receiver data is available when the interrupt is not masked (IER[0]=1) and the receiver FIFO level reaches the value stored in this register.

6.11.6 Flow Control Levels 'FCL & FCH'

The FCL and FCH registers are located at offsets 0x06 and 0x07 of the ICR respectively

Enhanced software flow control using XON/XOFF and hardware flow control using RTS#/CTS# and DTR#/DSR# are available when 950 mode trigger levels are enabled (ACR[5]=1). Improved flow control threshold levels are offered using Flow Control Lower trigger level ('FCL') and Flow Control Higher trigger level ('FCH') registers to provide a greater degree of flexibility when optimising the flow control performance. Generally, these facilities are only available in Enhanced mode.

In 650 mode, in-band flow control is enabled using the EFR register. An XOFF character is transmitted when the receiver FIFO exceeds the upper trigger level defined by FCR[7:6] as described in section 6.4.1. An XON is then sent when the FIFO is read down to the lower fill level. The flow control is enabled and the appropriate mode selected using EFR[3:0].

In 950 mode, the flow control thresholds defined by FCR[7:6] are ignored. In this mode threshold levels are programmed using FCL and FCH. When in-band flow control is enabled (defined by EFR[3:0]) and the receiver FIFO level ('RFL') reaches the value programmed in the FCH register, an XOFF is transmitted to stop the flow of serial data . The flow is resumed when the receiver FIFO fill level falls to below the value programmed in the FCL

register, at which point an XON character is sent. The FCL value of 0x00 is illegal.

For example if FCL and FCH contain 64 and 100 respectively, XOFF is transmitted when the receiver FIFO contains 100 characters, and XON is transmitted when sufficient characters are read from the receiver FIFO such that there are 63 characters remaining.

CTS/RTS and DSR/DTR out-of-band flow control use the same tigger levels as in-band flow control. When out-ofband flow control is enabled, RTS# (or DTR#) line is deasserted when the receiver FIFO level reaches the upper limit defined in the FCH and is re-asserted when the receiver FIFO is drained below the lower limit defined in FCL. When 950 trigger levels are enabled (ACR[5]=1), the CTS# flow control functions as in 650 mode and is configured by EFR[7]. However, when EFR[6] is set, RTS# is automatically de-asserted when RFL reaches FCH and re-asserted when RFL drops below FCL.

DSR# flow control is configured with ACR[2]. DTR# flow control is configured with ACR[4:3].

6.11.7 Device Identification Registers

The identification registers is located at offsets 0x08 to 0x0B of the ICR

The 950 offers four bytes of device dentification. The device ID registers may be read using offset values 0x08 to 0x0B of the Indexed Control Register. Registers ID1, ID2 and ID3 identify the device as an OX16C950 type and return 0x16, 0xC9 and 0x50 respectively. The REV register resides at offset 0x0B of ICR and identifies the revision of 950 core. This register returns 0x06 for the OXCF950.

6.11.8 Clock Select Register 'CKS'

The CKS register is located at offset 0x03 of the ICR

This register is cleared to 0x00 after a hardware reset to maintain compatibility with 16C550, but is unaffected by software reset. This allows the user to select a clock source and then reset the channel to work-around any timing glitches.

CKS[1:0]: Receiver Clock Source Selector

- $logic [00] \Rightarrow$ The output of baud rate generator (internal BDOUT#) is selected for the receiver clock.
- $logic [01] \Rightarrow$ The DSR# pin is selected for the receiver clock.
- $logic [10] \Rightarrow$ The output of baud rate generator (internal BDOUT#) is selected for the receiver clock.
- logic [11] ⇒ The transmitter clock is selected for the receiver. This allows RI# to be used for both transmitter and receiver.

CKS[2]: Reserved

This bit is unused in the OXCF950 and should be written with '0'.

CKS[3]: Receiver 1x clock mode selector

CKS[5:4]: Transmitter 1x clock or baud rate generator output (BDOUT) on DTR# pin

- logic $[00] \Rightarrow$ The function of the DTR# pin is defined by the setting of ACR[4:3].

- logic [11] \Rightarrow Reserved.

CKS[6]: Transmitter clock source selector

$\log 0 \Rightarrow$	The transmitter clock source is the output of
	the baud rate generator (550 compatibility).

logic 1 \Rightarrow The transmitter uses an external clock applied to the RI# pin.

CKS[7]: Transmitter 1x clock mode selector

6.11.9 Nine-bit Mode Register 'NMR'

The NMR register is located at offset 0x0D of the ICR

The 950 offers 9-bit data framing for industrial multi-drop applications. 9-bit mode is enabled by setting bit 0 of the Nine-bit Mode Register (NMR). In 9-bit mode the data length setting in LCR[1:0] is ignored. Furthermore as parity is permanently disabled, the setting of LCR[5:3] is also ignored.

The receiver stores the 9h bit of the received data in LSR[2] (where parity error is stored in normal mode). Note that the 950 provides a 128-deep FIFO for LSR[3:1]. The transmitter FIFO is 9bit wide and 128 deep. The user

should write the 9th (MSB) data bit in SPR[0] first and then write the other 8 bits to THR.

As parity mode is disabled, LSR[7] is set whenever there is an overrun, framing error or received break condition. It is unaffected by the contents of LSR[2] (Now the received 9th data bit).

In 9-bit mode, in-band flow control is disabled regardless of the setting of EFR[3:0] and the XON1/XON2/XOFF1 and XOFF2 registers are used for special character detection.

Interrupts in 9-Bit Mode:

While IER[2] is set, upon receiving a character with status error, a level 1 interrupt is asserted when the character and the associated status are transferred to the FIFO.

The 950 can assert an optional interrupt if a received character has its 9^h bit set. As multi-drop systems often use the 9^h bit as an address bit, the receiver is able to generate an interrupt upon receiving an address character. This feature is enabled by setting NMR[2]. This will result in a level 1 interrupt being asserted when the address character is transferred to the receiver FIFO.

In this case, as long as there are no errors pending, i.e. LSR[1], LSR[3], and LSR[4] are clear, '0' can be read back from LSR[7] and LSR[1], thus differentiating between an 'address' interrupt and receiver error or overrun interrupt in 9-bit mode. Note however that should an overrun or error interrupt actually occur, an address character may also reside in the FIFO. In this case, the software driver should examine the contents of the receiver FIFO as well as process the error.

The above facility produces an interrupt for recogni zing any 'address' characters. Alternatively, the user can configure 950 core to match the receiver data stream with up to four programmable 9-bit characters and assert a level 5 interrupt after detecting a match. The interrupt occurs when the character is transferred to the FIFO (See below).

NMR[0]: 9-bit mode enable

logic 0	\Rightarrow	9-bit	mode	is	disabled.

logic 1 \Rightarrow 9-bit mode is enabled.

NMR[1]: Enable interrupt when 9th bit is set

Special Character Detection

While the UART is in both 9-bit mode and Enhanced mode, setting IER[5] will enable detection of up to four 'address' characters. The least significant eight bits of these four programmable characters are stored in special characters 1 to 4 (XON1, XON2, XOFF1 and XOFF2 in 650 mode) registers and the 9th bit of these characters are programmed in NMR[5] to NMR[2] respectively.

NMR[2]: Bit 9 of Special Character 1 NMR[3]: Bit 9 of Special Character 2 NMR[4]: Bit 9 of Special Character 3 NMR[5]: Bit 9 of Special Character 4

NMR[7:6]: Reserved

Bits 6 and 7 of NMR are always cleared and reserved for future use.

6.11.10 Modem Disable Mask 'MDM'

The MDM register is located at offset 0x0E of the ICR This register is cleared after a hardware reset to maintain compatibility with 16C550. It allows the user to mask interrupts and control sleep operation due to individual modem lines or the serial input line.

MDM[0]: Disable delta CTS

- logic 0 ⇒ Delta CTS is enabled. It can generate a level 4 interrupt when enabled by IER[3]. Delta CTS can wake up the UART when it is asleep under auto-sleep operation.
- logic 1 \Rightarrow Delta CTS is disabled. It can not generate an interrupt or wake up the UART.

MDM[1]: Disable delta DSR

- logic 0 ⇒ Delta DSR is enabled. It can generate a level 4 interrupt when enabled by IER[3]. Delta DSR can wake up the UART when it is asleep under auto-sleep operation.
- logic 1 \Rightarrow Delta DSR is disabled. In can not generate an interrupt or wake up the UART.

MDM[2]: Disable Trailing edge RI

- logic 0 ⇒ Trailing edge RI is enabled. It can generate a level 4 interrupt when enabled by IER[3]. Trailing edge RI can wake up the UART when it is asleep under auto-sleep operation.
- logic 1 \Rightarrow Trailing edge RI is disabled. In can not generate an interrupt or wake up the UART.

MDM[3]: Disable delta DCD

- logic 0 → Delta DCD is enabled. It can generate a level 4 interrupt when enabled by IER[3]. Delta DCD can wake up the UART when it is asleep under auto-sleep operation.
- logic 1 \Rightarrow Delta DCD is disabled. In can not generate an interrupt or wake up the UART.

MDM[7:4]: Reserved

These bits must be set to '0000'

6.11.11 Readable FCR 'RFC'

The RFC register is located at offset 0x0F of the ICR

This read-only register returns the current state of the FCR register (Note that FCR is write-only). This register is included for diagnostic purposes.

6.11.12 Good-data status register 'GDS'

The GDS register is located at offset 0x10 of the ICR Good data status is set when the following conditions are true:

- ISR reads level0 (no interrupt), level2 or 2a (receiver data) or level3 (THR empty) interrupt.
- LSR[7] is clear i.e. no parity error, framing error or break in the FIFO.
- LSR[1] is clear i.e. no overrun error has occurred.

GDS[0]: Good Data Status

GDS[7:1]: Reserved

6.11.13 DMA Status Register 'DMS'

The DMS register is located at offset 0x11 of the ICR. This register is unused in the OXCF950 except for test purposes.

6.11.14 Port Index Register 'PIX'

The PIX register is located at offset 0x12 of the ICR. This read-only register gives the UART index. For a single channel device such as the OXCF950 this reads '0'.

6.11.15 Clock Alteration Register 'CKA'

The CKA register is located at offset 0x13 of the ICR. This register adds additional clock control mainly for isochronous and embedded applications. The register is effectively an enhancement to the CKS register.

This register is cleared to 0x00 after a hardware reset to maintain compatibility with 16C550, but is unaffected by software reset. This allows the user to select a clock mode and then reset the channel to work-around any timing glitches.

CKA[0]: Invert internal RX Clock

OXCF950 DATA SHEET V1.1

This allows the sense of the receiver clock to be inverted. The main use for this would be to invert an isochronous input clock so the falling edge were used for sampling rather than the rising edge.

CKA[1]: Invert internal TX clock

This allows the sense of the transmitter clock to be inverted. The main use for this would be to invert an isochronous input clock so the rising edge were used for data output rather than the falling edge.

CKA[2]: Invert DTR

This allows the DTR output signal to be inverted, which is most likely to be useful when DTR is selected as being the transmitter clock for isochronous applications.

6.11.16 Misc Data Register

The Misc Data Register allows the user to select access to either the local configuration registers or the local bus, when the OXCF950 is operating in Local Bus Mode. It has no effect when the OXCF950 is operating in Normal Mode.

Table 37 describes the MDR register operation.

MDR Bits	Description
7:1	Reserved for future use : '0' must be written to these.
0	Active low Local Bus Enable (Local Bus mode only). Setting this bit to '0' allows access to local bus. Setting this bit to '1' allows access to local configuration registers.

Table 37: MDR operation

Note that the operation of the MDR register in no way affects the operation of the UART.

7 SERIAL EEPROM SPECIFICATION

The OXCF950 can be configured using an optional serial electrically-erasable programmable read only memory (EEPROM). If the EEPROM is not present, the device will remain in its default configuration after reset. Although this may be adequate for some applications, many will benefit from the degree of programmability afforded by this feature. The EEPROM also allows accesses to the integrated UART, which can be useful for default setups.

The EEPROM interface supports a variety of serial EEPROM devices that have a proprietary serial interface known as MicrowireTM. This interface has four pins which supply the memory device with a clock, a chip-select, and serial data input and output lines. h order to read from such a device, a controller has to output serially a read command and address, then input serially the data. The interface controller has been designed to handle (auto detect) the following list of compatible devices that have a 16-bit data word format but differ in memory size (and hence the number of address bits). NM93C46 (64 WORDS), NM93C56 (128 WORDS), devices with 256 WORDS, 512 WORDs and 1024 WORDS.

The OXCF950 incorporates a controller module which reads data from the serial EPROM and writes data into the relevant register space. It performs this operation in a sequence which starts immediately after a CF/PCMCIA reset and ends either when the controller finds no

EEPROM is present or when it reaches the end of the eeprom data.

Following device configuration, driver software can access the serial EEPROM through four bits in the device-specific Local Configuration Register ESC[4:1]. Software can use this register to manipulate the device pins in order to read and modify the EEPROM contents as desired.

A Windows
 based utility to program the EEPROM is available. For further details please contact your local distributor.

Microwire[™] is a trade mark of National Semiconductor. For a description of Microwire[™], please refer to National Semiconductor data manuals.

7.1 EEPROM data Organisation

The serial EEPROM data is divided into 4 zones. The size of each zone is an exact multiple of 16-bit WORDs. Zone 0 is allocated to the header. An EEPROM program must contain a valid header before any further data is interrogated. The EEPROM can be programmed from the CF/PCMCIA Interface.. The general EEPROM data structure is shown in Table 5.

DATA Zone	Size (WORDS)	Description
0	One	Header
1	Two or more	CIS Configuration
2	One or more	Local Configuration registers
3	Multiples of two	Function Access

Table 38: EEPROM Data Format

7.2 Zone 0 : Header

The zone header identifies the EEPROM program as valid, and is the first value to be read and is at address 0 in the EEPROM. It has the following format:

Bits	Description
15:4	These bits should return 0xB12 to identify a valid program. Once it reads this value from these bits it sets bit [TBD] in the TBD register in the local register.
3	Reserved
2	1 = Zone 1 (CIS Configuration) data exists 0 = Zone 1 does not exist
1	1 = Zone 2 (Local Register Configuration) data exists 0 = Zone 2 does not exist
0	1 = Zone 3 (Function Access) data exists 0 = Zone 3 does not exist

Table 39: Zone 0 format

The programming data for each zone follows the proceeding zone if it exists. For example a header value of 0xB127 indicates that all zones exist and they follow one another, while 0XB123 indicates that only zone 2 and zone 3 exist.

7.3 Zone1 : Card Information Structure

This zone allows the user to provide custom tuple information for the Card Information Structure (CIS), overriding the default hard-coded tuple values found in the device. Downloading into this zone programs the internal RAM with the user's tuple data and automatically sets the source of the CIS to be this RAM, and <u>not</u> the hard coded value.

Note: if the CIS is to be modified using the EEPROM, tuple values presented to the host will be those

programmed into the RAM. The user must ensure that the RAM contains all the correct tuples for the particular application.

Tuple data bytes are interrogated until the specified number of type data-bytes have been collected in which case the EEPROM moves over to the next zone if it exists, or the EEPROM download terminates if no other zones are present.

The zone contains two areas to download to:

- Attribute memory (RAM address (0 to 127)
- Common memory (RAM address (128 to 255)

The first WORD in this zone describes how many bytes of data are present in each zone. The next words contain the tuple data. The first set of WORDS contain the tuples for the common memory (if present) followed by the tuple WORDS for the attribute memory.

Byte Number	Description				
	15	8	7 (
1 st WORD	Number of tuple bytes in Common Me Note : Must be a value of multiple of 2	emory (N)	Number of tuple bytes in Attribute Memory (M) Note : Must be a value of multiple of 2		
2 nd WORD	Attribute Mem.Tuple Byte 1		Attribute Mem.Tuple Byte 0		
3 rd WORD	Attribute Mem.Tuple Byte 3		Attribute Mem.Tuple Byte 2		
(N + 1) th WORD	Attribute Mem.Tuple Byte N-1		Attribute Mem.Tuple Byte N-2		
(N + 2) th WORD	Common Mem. Tuple Byte 1		Common Mem. Tuple Byte 0		
(N + 3) th WORD	Common Mem. Tuple Byte 3		Common Mem. Tuple Byte 2		
(N + M + 1) th WORD	Common Mem. Tuple Byte M-1		Common Mem. Tuple Byte M-2		

Table 40: Word format for Zone 1

7.4 Zone 2 : Local Register Configuration

The Zone2 region of EEPROM contains the program value of the vendor-specific Local Configuration Registers using one or more configuration WORDs. Registers are selected using a 7-bit byte-offset field. This offset value is the offset from address 8 (allowing addresses 0 to 7 to be reserved for function access).

Bits	Description
15	 '0' = There are no more configuariton WORDs to follow in Zone 2. Move to next available zone or end EEPROM program if no more zones are enabled in the header. 1'1 = There is another configuration WORD to follow for the Local Configuration Registers
14:8	Local Register address (in IO space). Valid address range is 8 to 15
7:0	8-bit value of the register to be programmed

 Table 41: Word format for Zone 2

7.5 Zone 3 : Function Access (UART)

Zone 3 allows the UART to be pre-configured, prior to any CF/PCMCIA accesses. This is very useful when the UART needs to run with (typically generic) device drivers and these drivers are not capable of utilising the enhanced features/modes of the UART (e.g. 950 mode) that are required for high performance. By using function access, the UART registers can be accessed (setup) via the EEPROM to customize the UART features before control is handed to the device drivers.

Each 8-bit access is equivalent to accessing the UART function through IO space (addresses 0 to 7), with the exception that a function read access does not return any data (it is discarded). The UART function behaves as though these function accesses via the EEPROM were corresponding CF/PCMCIA access.

Each entry for zone 3 comprises of 2 16-bit words. The format is as shown.

1 st WORD (of WORD pair)								
Bits Description								
15	Value = 1							
14:12	Reserved (write 0's)							
11	0 = Function read access							
	1 = Function write access							
10:8	Reserved (write 0's)							
7:0	IO address to access (valid values 0 to 7)							

Table 42: Zone 3 (first WORD) format

2 nd WORD (of WORD pair)									
Bits Description									
15	'1' = another function access WORD pair to follow								
	'0' = no more function access WORD pairs								
14:8	Reserved (write 0's)								
7:0	Data to be written to specified addresses. Field is unused for function access READS (set to 0)

V _{DD}	Supply voltage	Commercial	3.15	3.45	V
V _{IH}	Input high voltage	CMOS Interface Note1 CMOS Schmitt trigger	0.7 V _{DD} 1.6		V
V _{IL}	Input low voltage	CMOS Interface Note 1 CMOS Schmitt trigger		0.2 V _{DD} 1.2	V
V _H	Schmitt Hysteresis	CMOS	0.6	0.8	V
C⊩	Capacitance of input buffers			5.0	pF
Col	Capacitance of output buffers			10.0	pF
ΙH	Input high leakage current	$V_{in} = V_{DD}$	-10	10	μA
١L	Input low leakage current	Vin = Vss	-10	10	μA
Vон	Output high voltage	I _{OH} = 2 mA Note2	2.4		V
Vol	Output low voltage	IOL = 2 mA Note2		0.4	V
loz	3-state output leakage current		-10	10	μA
I _{ST}	Static current Note3	$V_{in} = V_{DD} \text{ or } V_{SS}$		40	μA
Icc	Operating supply current in normal mode Note3	f _{CK} = 1.8432 MHz f _{CK} = 8.192 MHz f _{CK} = 50.00 MHz	2.2 3.0 5.0	2.4 3.3 5.6	mA
	Operating supply current in sleep mode Note3	f _{CK} = 1.8432 MHz f _{CK} = 8.192 MHz f _{CK} = 50.00 MHz	-	2.1 2.8 4.2	mA

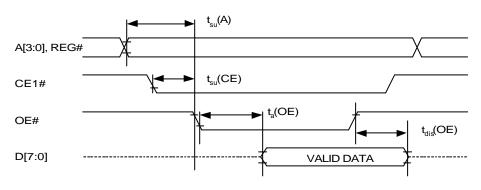

Note 1: All input buffers are CMOS with the exception of RESET, Z_CTS,Z_DSR, Z_DCD and Z_RI which are Schmitt triggered.

Note 2: All output buffers are 2 mA drive capability, with the exception of the EEPROM signals, Z_IOIS16, Z_IREQ and the UART output signals which are all 1 mA drive capability.

Note 3: Divider ratio of 1. These are sample measured figures.

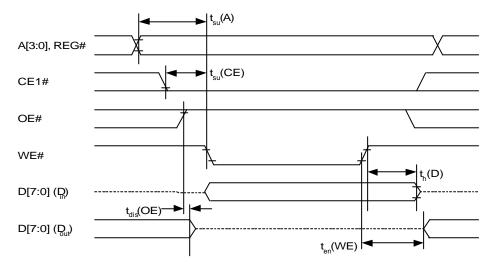

10 TIMING WAVEFORMS / AC CHARACTERISTICS

10.1 Common Memory Access
