# TV and VTR stereo/dual sound processor with digital identification

## TDA9847

### FEATURES

- Supply voltage 5 to 8 V
- Source selector
- Stereo matrix
- AF inputs for external stereo AF signals (SCART or NICAM)
- AF outputs for main and SCART
- LED operation mode indication (stereo and dual)
- High identification reliability.

### GENERAL DESCRIPTION

The TDA9847 is a stereo/dual sound processor for TV and VTR sets. Its identification ensures safe operation by using internal digital PLL technique with extremely small bandwidth, synchronous detection and digital integration (switching time maximum 2.0 s; identification concerning the main functions).

### QUICK REFERENCE DATA

XTAL	23	10 MHz crystal input
C3	24	control input Port C3

## TV and VTR stereo/dual sound processor with digital identification

TDA9847

### FUNCTIONAL DESCRIPTION

#### AF signal handling

The input AF signals, derived from the two sound carriers, are processed in analog form using operational amplifiers. De-matrixing uses the technique of two amplifiers processing the AF signals. Finally, a source selector provides the facility to route the mono signal through to the outputs ('forced mono').

De-emphasis is performed by two RC low-pass filter networks with internal resistors and external capacitors. This provides a frequency response with the tolerances given in Fig.4.

A source selector, controlled via the control input ports allows selection of the different modes of operation in accordance with the transmitted signal. The device was designed for a nominal input signal (FM: 54% modulation is equivalent to  $\Delta f = \pm 27$  kHz) of 250 mV RMS value ( $V_{i1}$  and  $V_{i2}$ ) and for a nominal input signal (AM:  $m = 0.54$ ) of 500 mV RMS value ( $V_{i1}$ ), respectively 250 mV RMS ( $V_{i3}$  and  $V_{i4}$ ). A nominal gain of 6 dB for  $V_{i1}$  and  $V_{i2}$  signals (0 dB for  $V_{i1}$  signal (AM sound)) and 6 dB for  $V_{i3}$  and  $V_{i4}$  signals is built-in. By using rail-to-rail operational amplifiers, the clipping level (THD  $\leq 1.5\%$ ) is 1.60 V RMS for  $V_P = 5$  V and 2.65 V RMS for  $V_P = 8$  V at outputs  $V_{o1}$  to  $V_{o3}$  and  $V_{o4}$ . Care has been taken to minimize switching plops. Also total harmonic distortion and random noise are considerably reduced.

#### Identification

The pilot signal is fed via an external RC high-pass filter and single tuned LC band-pass filter to the input of a gain controlled amplifier. The external LC band-pass filter in combination with the external RC high-pass filter should have a loaded Q-factor of approximately 40 to 50 to ensure the highest identification sensitivity. By using a fixed coil ( $\pm 5\%$ ) to save the alignment (see Fig.2), a Q-factor of approximately 12 is proposed. This may cause a loss in sensitivity of approximately 2 to 3 dB. A digital PLL circuit generates a reference carrier, which is synchronized with the pilot carrier. This reference carrier and the gain controlled pilot signal are fed to the AM-synchronous demodulator. The demodulator detects the identification signal, which is fed through a low-pass filter with external capacitor CLP (pin 5) to a Schmitt trigger for pulse shaping and suppression of LOW level spurious signal components. This is a measure against mis-identification.

The identification signal is amplified and fed through an AGC low-pass filter with external capacitor CAGC (pin 4)

to obtain the AGC voltage for controlling the gain of the pilot signal amplifier.

The identification stages consist of two digital PLL circuits with digital synchronous demodulation and digital integrators to generate the stereo or dual sound identification bits which can be indicated via LEDs.

A 10 MHz crystal oscillator provides the reference clock frequency. The corresponding detection bandwidth is larger than  $\pm 50$  Hz for the pilot carrier signal, so that  $f_p$ -variations from the transmitter can be tracked in the event of missing synchronization with the horizontal frequency  $f_H$ . However the detection bandwidth for the identification signal is made small ( $\pm 1$  Hz) to reduce mis-identification.

Figure 2 shows an example of the alignment-free  $f_p$  band-pass filter. To achieve the required  $Q_L$  of around 12, the  $Q_0$  at  $f_p$  of the coil was chosen to be around 25 (effective  $Q_0$  including PCB influence). Using coils with other  $Q_0$ , the RC-network ( $R_{FP}$  and  $C_{FP}$ ) has to be adapted accordingly. It is assumed that the loss factor  $\tan \delta$  of the resonance capacitor is  $\leq 0.01$  at  $f_p$ .

Copper areas under the coil might influence the loaded Q and have to be taken into account. Care has also to be taken in environments with strong magnetic fields when using coils without magnetic shielding.

#### Control input ports

The complete IC is controlled by the four control input ports C1, C2, C3 and C4. Which AF output channel pair can be selected is determined by the control input Port C4 [LOW: main; HIGH: SCART; 3-state: preset position (see Section "General information")]. With the other control input ports C1, C2 and C3 the user can select between different AF sources in accordance with the transmitter status (see Tables 1 and 2). Finally, Schmitt triggers are added in the input Port interfaces to suppress spikes on the control lines C1, C2, C3 and C4.

After a Power-On Reset (POR) both registers are reset (mute mode for both AF channel pairs). After some time ( $\leq 1$  ms), when the POR is automatically deactivated, the switch positions of the main channel (C4 = LOW) are changed in accordance with the other control input Port levels. If C4 is HIGH after a POR, the switch positions of the SCART channel cannot change. The reason is, that the main register is reset (mute mode; see Table 1). Thus, at first the main register byte has to be changed out of the mute function, e.g. sound mute.

## TV and VTR stereo/dual sound processor with digital identification

TDA9847

After that, when C4 is HIGH (see Table 2), the switch positions of the SCART channel are changed in accordance with the other control line levels.

When the supply voltage of the TDA9847 is not connected (standby function), the control lines remain undisturbed.

The logic level combination 1000 of the control input ports (C4, C3, C2 and C1) is not allowed (see Tables 1 and 2).

### Operating mode selection

Tables 1 and 2 show the different operating modes of this stereo decoder.

#### MUTE MODE

This IC has two different mute modes:

1. Mute mode.
2. Sound mute mode.

In the mute mode, when all control input lines are set LOW, all AF channels are muted ('fast mute'). Finally, the integrators are reset provided the user does not leave this mode (identification is disabled). When the user changes this mode, the identification circuit starts with the detection.

In the sound mute mode each AF channel can be separately muted (0100 = main and 1100 = SCART). The identification circuit is activated and the LEDs are on or off in accordance with the detection status of this circuit.

#### MONO MODE

For the transmitter status mono the user must set the TDA9847 in the mono mode with X001 or X010 (see Tables 1 and 2). The level combination X011 is reserved for the AM sound (standard L), because in this mode the de-emphasis is deactivated and the gain of the AF signal from input to output is reduced from 6 dB to 0 dB. At the AF outputs the signal has the same level for standards with FM or AM modulated sound assuming the same modulation degree.

#### STEREO MODE

In this mode the choice between stereo and mono ('forced mono') signals is common for both AF channel pairs. The mode for main and SCART is achieved by control of the main channel (see Tables 1 and 2).

#### DUAL MODE

In this mode there is no restriction to select AF inputs and outputs independently in both channels.

#### EXTERNAL MODE

External sound sources, e.g. from SCART input, are fed to both AF channel pair outputs. When the user chooses the external mode of the main channel (see Table 1), the identification circuit is still running, but the LEDs are switched-off.

### Programming of the main and SCART register

#### GENERAL INFORMATION

The switch positions of both AF channels are directly controlled by the data of the main and SCART register. These registers are programmable by a microcontroller.

In the 3-state mode the logic content of the C1, C2 and C3 control lines remains stored in the registers for main and SCART, so the switch positions in the source selector do not change. The logic content of these control lines can be changed without changing the switch positions of the source selector (preset position) to prepare the new operating mode selection for the main or SCART channel. The execution of this new mode is achieved by leaving the preset position (3-state): When the C4 level goes LOW, the logic content of the control lines C1, C2 and C3 are valid for the main channel (see Table 1) and in the event of HIGH the C1, C2 and C3 are valid for the SCART channel (see Table 2).

The identification bits and the control lines influence the operating mode selection for the AF switches in the source selector and de-matrix, e.g. both AF channels are programmed in the mono mode (X001, see Tables 1 and 2). The LEDs are switched-off. When the identification circuit detects the stereo identification frequency ( $f_s = 117$  Hz) the de-matrix is immediately switched in the stereo mode without changing the control line levels. The stereo signals are routed to all AF outputs. In the event of dual frequency detection ( $f_D = 274$  Hz) both dual sounds are fed to the AF output pairs.

#### MICROCONTROLLER WITH 3-STATE OUTPUT PORTS

Figure 10 shows an example of an application circuit for TDA9847 ( $V_P = 4.5$  to  $8.8$  V) in conjunction with a microcontroller, which has a LOW/high-ohmic/HIGH output port to control the main and SCART channel (C4 control line). For the C1, C2 and C3 line the microcontroller requires only LOW/HIGH output ports. Two resistors  $R_{C4A}$  and  $R_{C4B}$  are necessary for the C4 line to generate the 3-state voltage. The values and tolerances of these components are given in Fig.10.

## TV and VTR stereo/dual sound processor with digital identification

TDA9847

When the microcontroller has only open drain ports available for the C1, C2 and C3 control line, external pull-up resistors must be connected to these control lines.

Figure 7 shows an example of a timing diagram to program the main and SCART register of the TDA9847 with a microcontroller via the control lines C1, C2, C3 and C4. Both registers are programmed with the same control line levels: C1 = LOW, C2 = HIGH and C3 = LOW. The dual identification frequency is detected and the dual LED is switched-on. The A-signal (dual mode) is fed to all AF outputs (see Tables 1 and 2). This is shown in the beginning of this timing diagram.

The second period of time shows the programming of the external mode (C3 goes to HIGH: CC-signal) for the main channel. The switch positions are immediately changed to the external AF source, because the C4 level is LOW. The dual LED is switched-off by the logic (see Section "External mode").

The next periods of time show the way to change the switch positions for the SCART channel to route B-signals to the AF outputs (dual mode: BB). At first the control output Port of the microcontroller for the C4 line goes into the high ohmic state. The changing of the C1, C2 or C3 level has no influence on the register data. In the timing diagram the C1 level changes from LOW-to-HIGH and the C3 level goes from HIGH-to-LOW. In the next steps the C4 line goes from 3-state-to-HIGH, and the level of the other control lines are valid for the SCART channel, and the B-signals are fed (dual mode: BB) to the AF outputs of the main channel.

After some time in this example the C1 and C2 levels change from HIGH-to-LOW and the C3 level goes from LOW-to-HIGH (sound mute). The SCART channel is immediately muted, because the level of the C4 line is HIGH.

The last period of time shows the programming of the dual mode (AA) for the main channel. At first the control output Port of the microcontroller for the C4 line goes into the high ohmic state. The changing of the C1, C2 or C3 level has no influence on the register data. The switch positions of the SCART channel stay in the sound mute.

In the 3-state mode the C2 level changes from LOW-to-HIGH, and the C3 level goes from HIGH-to-LOW. When the C4 level is LOW, the level of the other control lines are valid for the main channel. The A-signal (dual mode) is fed to the main outputs.

The operation mode mute (see Table 1) can be achieved from any position of the C4 control line without going via 3-state.

Figure 5 shows the hold and set-up time of the C1, C2 and C3 control line in the 3-state mode, see Chapter "Characteristics".

### MICROCONTROLLER WITH LOW/HIGH OUTPUT PORTS

Figure 11 shows an example of an application circuit for TDA9847 ( $V_P = 4.5$  to  $8.8$  V) in conjunction with a microcontroller, which has open drain output ports to control the main and SCART channel. Four resistors and two output ports of the microcontroller are necessary to generate the 3-state voltage. The other control lines have a pull-up resistor (10 k $\Omega$ ) in the event of open drain output stages. These resistors are not necessary for LOW/HIGH output ports of the microcontroller having internal pull-up or push-pull stages. The values and tolerances of these components are given in this figure. Table 4 shows the conversion logic truth table.

For information about programming the different operation mode selections see Section "Operating mode selection".

### Power supply

The different supply voltages and currents required for the analog and digital circuits are derived from an internal band-gap reference circuit. The AF reference voltage is  $\frac{1}{2}V_P$ . For a fast setting to  $\frac{1}{2}V_P$  an internal start-up circuit is added. A good ripple rejection is achieved with the external capacitor  $C_{ref} = 100 \mu\text{F}/16$  V in conjunction with the high ohmic input of the  $\frac{1}{2}V_P$  pin (pin 8). No additional DC load on this pin is allowed.

### Power-On Reset (POR)

When a POR is activated by switching on the supply voltage or because of a supply voltage breakdown, the 117/274 Hz DPLL, the 117/274 Hz integrator and the logic will be reset. Both AF channels (main and SCART) are muted ( $\leq 1$  ms).

### ESD protection

All pins are ESD protected. The protection circuits represent the latest state of the art.

### Internal circuit

The internal pin configuration is given in Fig.7.

### Notes to the characteristics

- $V_o = 0.5$  V (RMS value);  $f = 1$  kHz.
- Without de-emphasis capacitors with respect to nominal gain.
- In dual mode: A (B)-signal into B (A) channel; in stereo mode: R-signal into left channel; L-signal = 0.
- Tuner input signal, measured with PCALH reference front end ( $1/2$ EMF,  $75 \Omega$ , 2T/20T/white bar, 100% video) and  $\text{PC}/\text{SC}_1 = 13$  dB;  $\text{PC}/\text{SC}_2 = 20$  dB. The pilot band-pass has to be aligned.
- Bandwidth of the pilot BP-filter  $B_{-3 \text{ dB}} = 1.2$  kHz.  $V_{i2}$  input driven with identification-modulated pilot carrier and white noise.
- Identification window is defined as twice the pull-in frequency range (lower plus upper side) of identification PLL (steady detection) plus window increase due to integrator (fluctuating detection).
- The maximal total system identification time on is equal to  $t_{\text{ident(on)}}$  plus  $t_{\text{acqui AGC}}$ .
- The maximal total system identification time off is equal to  $t_{\text{ident(off)}}$ .

**TDA9847****SOLDERING****Plastic dual in-line packages**

BY DIP OR WAVE

The maximum permissible temperature of the solder is 260 °C; this temperature must not be in contact with the joint for more than 5 s. The total contact time of successive solder waves must not exceed 5 s.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified storage maximum. If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

## REPAIRING SOLDERED JOINTS

Apply a low voltage soldering iron below the seating plane (or not more than 2 mm above it). If its temperature is below 300 °C, it must not be in contact for more than 10 s; if between 300 and 400 °C, for not more than 5 s.

**Plastic small outline packages**

BY WAVE

During placement and before soldering, the component must be fixed with a droplet of adhesive. After curing the adhesive, the component can be soldered. The adhesive can be applied by screen printing, pin transfer or syringe dispensing.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder bath is 10 s, if allowed to cool to less than 150 °C within 6 s. Typical dwell time is 4 s at 250 °C.

A modified wave soldering technique is recommended using two solder waves (dual-wave), in which a turbulent wave with high upward pressure is followed by a smooth laminar wave. Using a mildly-activated flux eliminates the need for removal of corrosive residues in most applications.

## BY SOLDER PASTE REFLOW

Reflow soldering requires the solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the substrate by screen printing, stencilling or pressure-syringe dispensing before device placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt, infrared, and vapour-phase reflow. Dwell times vary between 50 and 300 s according to method. Typical reflow temperatures range from 215 to 250 °C.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 min at 45 °C.

## REPAIRING SOLDERED JOINTS (BY HAND-HELD SOLDERING IRON OR PULSE-HEATED SOLDER TOOL)

Fix the component by first soldering two, diagonally opposite, end pins. Apply the heating tool to the flat part of the pin only. Contact time must be limited to 10 s at up to 300 °C. When using proper tools, all other pins can be soldered in one operation within 2 to 5 s at between 270 and 320 °C. (Pulse-heated soldering is not recommended for SO packages.)

For pulse-heated solder tool (resistance) soldering of VSO packages, solder is applied to the substrate by dipping or by an extra thick tin/lead plating before package placement.

**TDA9847****DEFINITIONS**

<b>Data sheet status</b>	
Objective specification	This data sheet contains target or goal specifications for product development.
Preliminary specification	This data sheet contains preliminary data; supplementary data may be published later.
Product specification	This data sheet contains final product specifications.
<b>Limiting values</b>	
Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.	
<b>Application information</b>	
Where application information is given, it is advisory and does not form part of the specification.	

**LIFE SUPPORT APPLICATIONS**

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.
