Data Sheet   1998-07-27

SLx 24C08/16/P Revision History:		Current Version: 1998-07-27
Previous Version:		06.97
Page (in previous Version)	Page (in current Version)	Subjects (major changes since last revision)
3	3	Text was changed to "Typical programming time 5 ms for up to 16 bytes".
4, 5	4, 5	CS0, CS1 and CS2 were replaced by n.c.
5	–	The paragraph "Chip Select (CS0, CS1, CS2)" was removed completely.
5	5	WP = V_{CC} protects the ~~upper half~~ entire memory.
11, 12	11, 12	The erase/write cycle is finished latest after ~~10~~ 8 ms.
15	15	Figure 11: second command byte is a **CSR** and not CSW.
21	21	The write or erase cycle is finished latest after ~~10~~ 4 ms.
19	24	"Capacitive load …" were added.
25	25	Some timings were changed.
25	25	The line "erase/write cycle" was removed.
25	25	Chapter 8.4 "Erase and Write Characteristics" has been added.

I²C Bus

Purchase of Siemens I²C components conveys the license under the Philips I²C patent to use the components in the I²C system provided the system conforms to the I²C specifications defined by Philips.

SIEMENS

8/16 Kbit (1024/2048 × 8 bit) Serial CMOS EEPROMs, I²C Synchronous 2-Wire Bus, Page Protection Mode™

SLx 24C08/16/P

Features

- **Data EEPROM internally organized as 1024/2048 bytes and 64/128 pages × 16 bytes**
- **Page protection mode, flexible page-by-page hardware write protection**
  - Additional protection EEPROM of 64/128 bits, 1 bit per data page
  - Protection setting for each data page by writing its protection bit
  - Protection management without switching WP pin
- **Low power CMOS**
- V_{CC} **= 2.7 to 5.5 V operation**
- **Two wire serial interface bus, I²C-Bus compatible**
- **Filtered inputs for noise suppression with Schmitt trigger**
- **Clock frequency up to 400 kHz**
- **High programming flexibility**
  - Internal programming voltage
  - Self timed programming cycle including erase
  - Byte-write and page-write programming, between 1 and 16 bytes
  - Typical programming time 5 ms for up to 16 bytes
- **High reliability**
  - Endurance 10^6 cycles [1]
  - Data retention 40 years [1]
  - ESD protection 4000 V on all pins
- **8 pin DIP/DSO packages**
- **Available for extended temperature ranges**
  - Industrial: − 40 °C to + 85 °C
  - Automotive: − 40°C to + 125 °C

P-DIP-8-4

P-DSO-8-3

Pin Configuration (top view)

Pin Definitions and Functions

Table 1

Pin No.	Symbol	Function
1, 2, 3	N.C.	Not connected
4	V_{SS}	Ground
5	SDA	Serial bidirectional data bus
6	SCL	Serial clock input
7	WP	Write protection input
8	V_{CC}	Supply voltage

Pin Description

Serial Clock (SCL)

The SCL input is used to clock data into the device on the rising edge and to clock data out of the device on the falling edge.

Serial Data (SDA)

SDA is a bidirectional pin used to transfer addresses, data or control information into the device or to transfer data out of the device. The output is open drain, performing a wired AND function with any number of other open drain or open collector devices. The SDA bus requires a pull-up resistor to V_{CC}.

Write Protection (WP)

WP switched to V_{SS} allows normal read/write operations.

WP switched to V_{CC} protects the entire EEPROM against changes (hardware write protection).

Additionally write protection is managed by a protection bit associated to each page. (refer to **chapter 7** Page Protection Mode[TM])

2 Description

The SLx 24C08/16/P device is a serial electrically erasable and programmable read only memory (EEPROM), organized as 1024/2048 × 8 bit. The data memory is divided into 64/128 pages. The 16 bytes of a page can be programmed simultaneously. Each page may be protected individually against changes by its associated protection bit.

The device conforms to the specification of the 2-wire serial I²C-Bus. Low voltage design permits operation down to 2.7 V with low active and standby currents.

The device operates at 5.0 V ± 10% with a maximum clock frequency of 400 kHz and at 2.7 ... 4.5 V with a maximum clock frequency of 100 kHz. The device is available as 5 V type (V_{CC} = 4.5 … 5.5 V) with two temperature ranges for industrial and automotive applications and as 3 V type (V_{CC} = 2.7 … 5.5 V) for industrial applications. The EEPROMs are mounted in eight-pin DIP and DSO packages or are also supplied as chips.
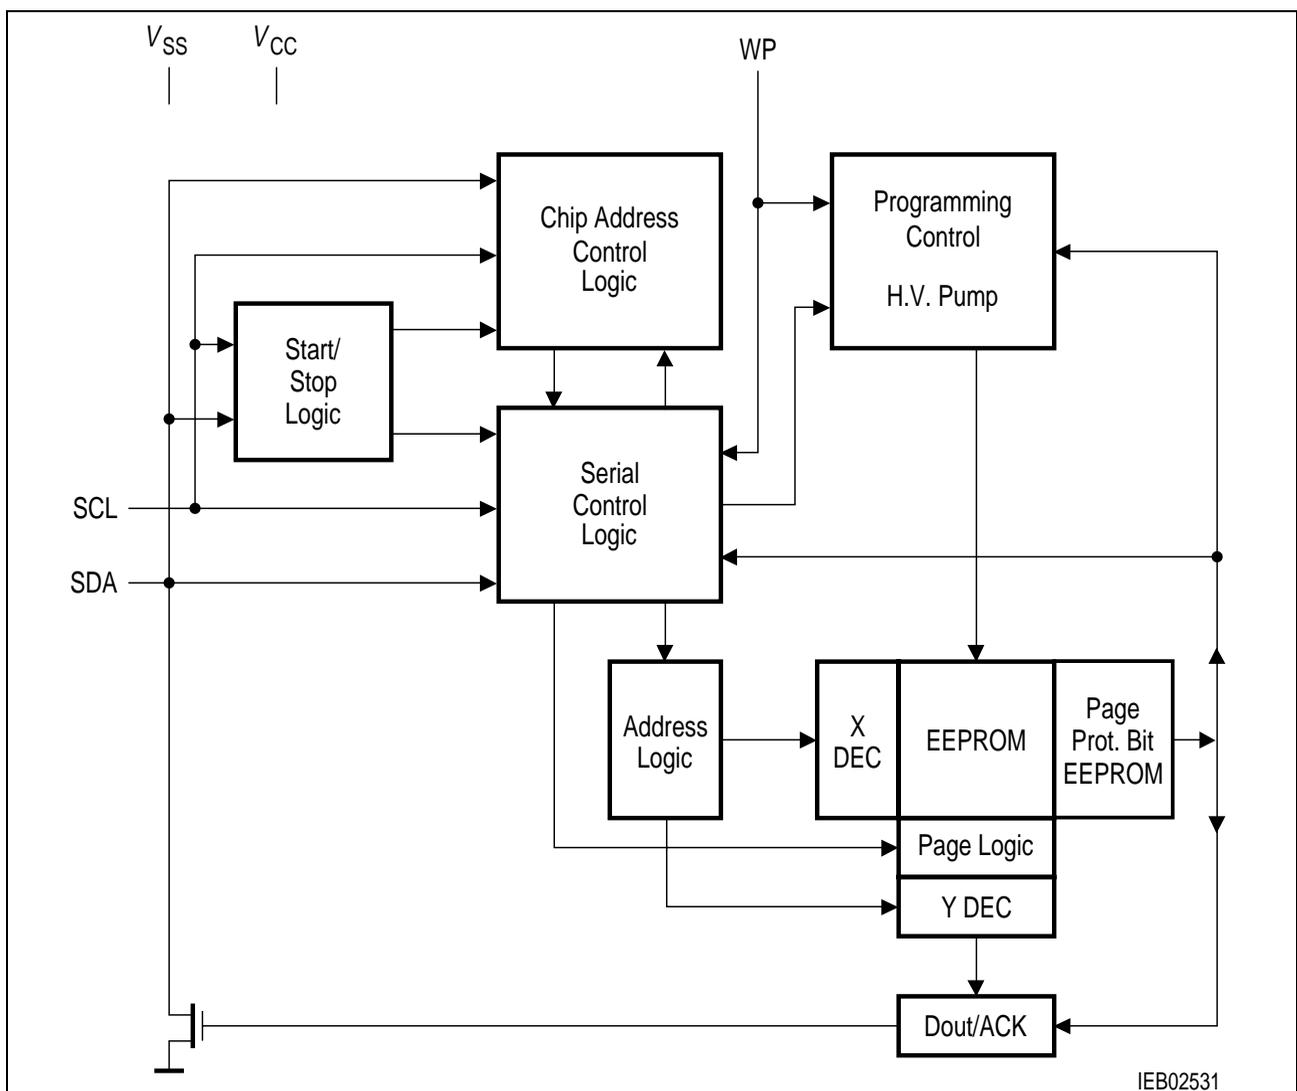

Figure 2
Block Diagram

3   I²C-Bus Characteristics

The SLx 24C08/16/P devices support a master/slave bidirectional bus oriented protocol in which the EEPROM always takes the role of a slave.
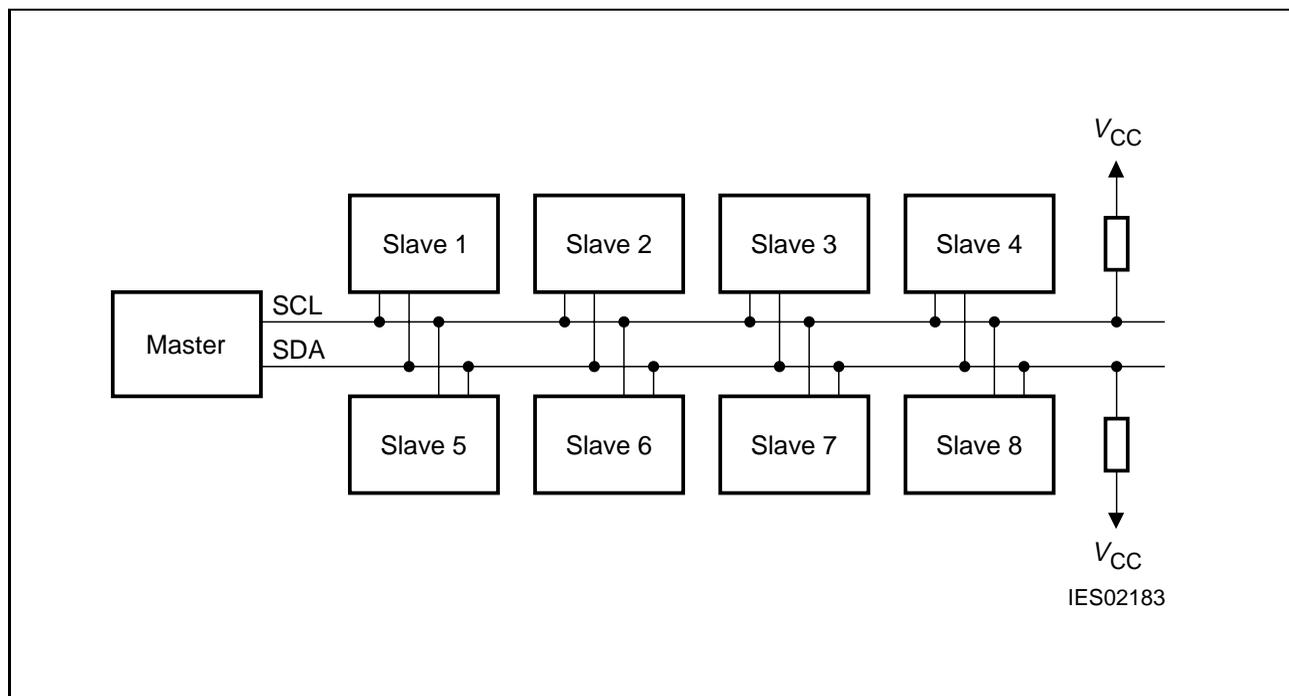

Figure 3
Bus Configuration

Master   Device that initiates the transfer of data and provides the clock for both transmit and receive operations.

Slave   Device addressed by the master, capable of receiving and transmitting data.

Transmitter The device with the SDA as output is defined as the transmitter. Due to the open drain characteristic of the SDA output the device applying a low level wins.

Receiver   The device with the SDA as input is defined as the receiver.

The conventions for the serial clock line and the bidirectional data line are shown in **figure 4**.
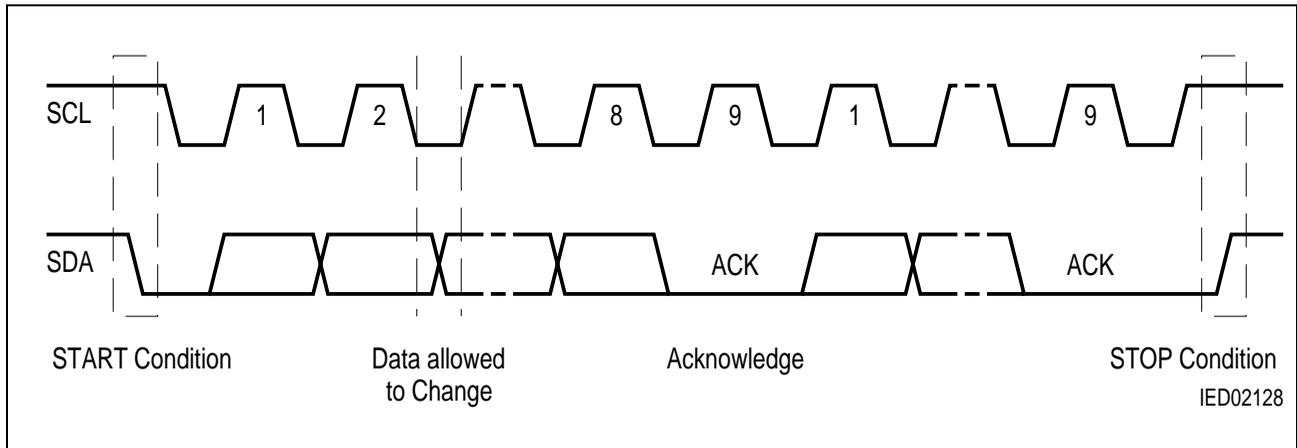

Figure 4
I^{2}C-Bus Timing Conventions for START Condition, STOP Condition, Data Validation and Transfer of Acknowledge ACK

|	
Standby	Mode in which the bus is not busy (no serial transmission, no programming): both clock (SCL) and data line (SDA) are in high state. The device enters the standby mode after a STOP condition or after a programming cycle.
START Condition	High to low transition of SDA when SCL is high, preceding all commands.
STOP Condition	Low to high transition of SDA when SCL is high, terminating all communications. A STOP condition initiates an EEPROM programming cycle. A STOP condition after reading a data byte from the EEPROM initiates the Standby mode.
Acknowledge	A successful reception of eight data bits is indicated by the receiver by pulling down the SDA line during the following clock cycle of SCL (ACK). The transmitter on the other hand has to release the SDA line after the transmission of eight data bits. The EEPROM as the receiving device responds with an acknowledge, when addressed. The master, on the other side, acknowledges each data byte transmitted by the EEPROM and can at any time end a read operation by releasing the SDA line (no ACK) followed by a STOP condition.
Data Transfer	Data must change only during low SCL state, data remains valid on the SDA bus during high SCL state. Nine clock pulses are required to transfer one data byte, the most significant bit (MSB) is transmitted first.

4 Device Addressing and EEPROM Addressing

After a START condition, the master always transmits a Command Byte CSW or CSR. After the acknowledge of the EEPROM a Control Byte follows, its content and the transmitter depend on the previous Command Byte. The description of the Command and Control Bytes is shown in **table 2**.

Command Byte **Selects operation:** the least significant bit b0 is low for a write operation (Chip Select Write Command Byte CSW) or set high for a read operation (Chip Select Read Command Byte CSR).

Contains address information: in the CSW Command Byte, the bit positions b2 or b3 to b1 are decoded for the two or three uppermost EEPROM address bits A9 or A10 to A8 (in the CSR Command Byte, the bit positions b3 to b1 are left undefined).

Control Byte **Following CSW (b0 = 0):** contains the eight lower bits of the EEPROM address (EEA) bit A7 to A0, or an additional command byte for the handling of the protection bit.

Following CSR (b0 = 1): contains the data read out, transmitted by the EEPROM. The EEPROM data are read as long as the master pulls down SDA after each byte in order to acknowledge the transfer. The read operation is stopped by the master by releasing SDA (no acknowledge is applied) followed by a STOP condition.

Table 2
Command and Control Byte for I^2C-Bus Addressing of Chip and EEPROM

	Definition								Function
	b7	b6	b5	b4	b3	b2	b1	b0	
CSW	1	0	1	0	A10	A9	A8	0	Chip Select for Write
CSR	1	0	1	0	x	x	x	1	Chip Select for Read
EEA	A7	A6	A5	A4	A3	A2	A1	A0	EEPROM address

The device has an internal address counter which points to the current EEPROM address.

The address counter is incremented
– after a data byte to be written has been acknowledged, during entry of further data byte
– during a byte read, thus the address counter points to the following address after reading a data byte.

The timing conventions for read and write operations are described in **figures 5** and **6**.
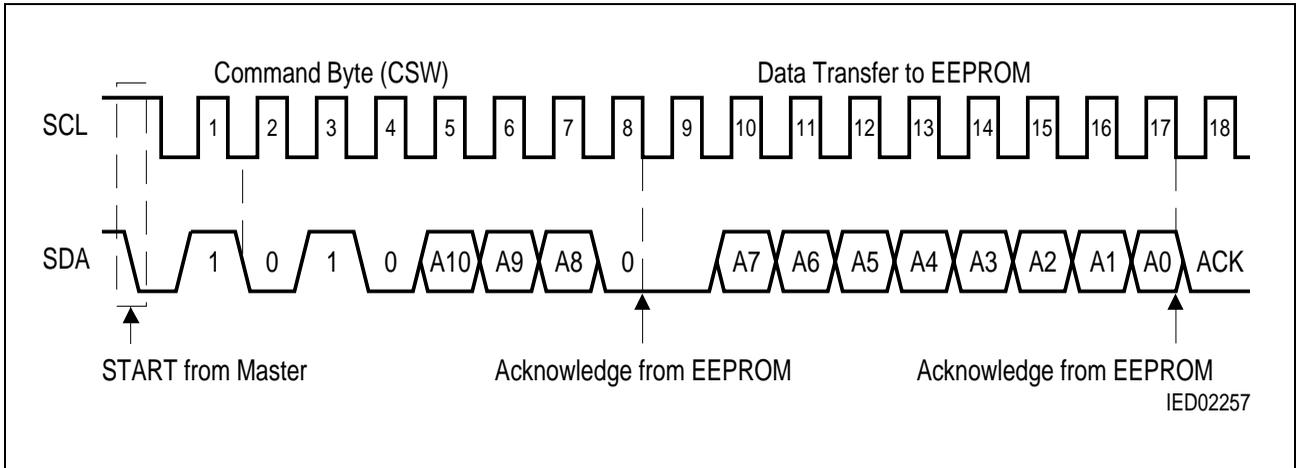

**Figure 5**
Timing of the Command Byte CSW
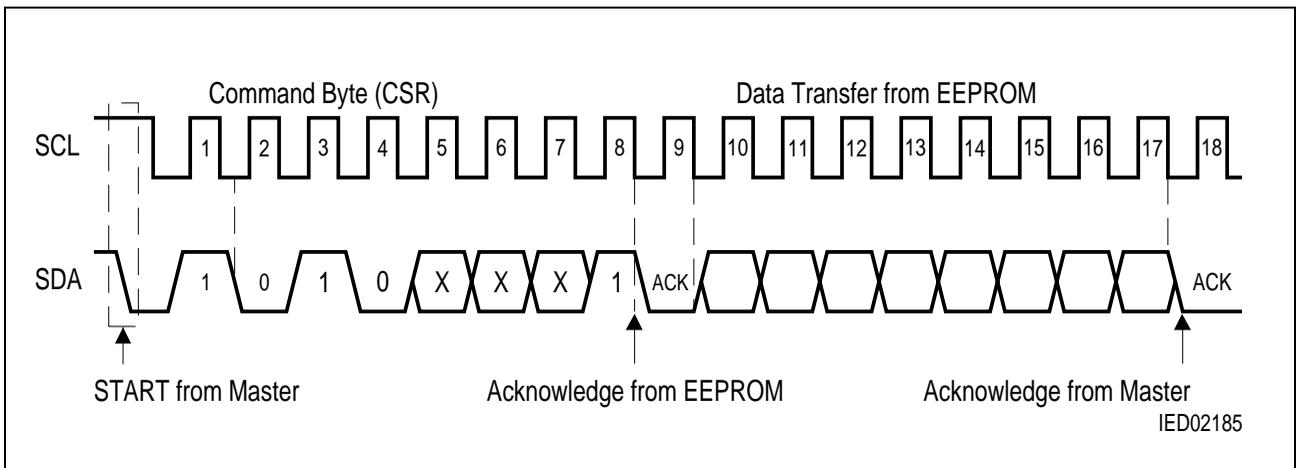

Figure 6
Timing of the Command Byte CSR

5 Write Operations

Changing of the EEPROM data is initiated by the master with the command byte CSW. Depending on the state of the Write Protection pin WP and of the Protection Bits (refer to **chapter 7** Page Protection Mode™) either one byte (Byte Write) or up to 16 bytes (Page Write) are modified in one programming procedure.

5.1 Byte Write

Address Setting
After a START condition the master transmits the Chip Select Write byte CSW. The EEPROM acknowledges the CSW byte during the ninth clock cycle. The following byte with the EEPROM address (A0 to A7) is loaded into the address counter of the EEPROM and acknowledged by the EEPROM.

Transmission of Data
Finally the master transmits the data byte which is also acknowledged by the EEPROM into the internal buffer.

Programming Cycle
Then the master applies a STOP condition which starts the internal programming procedure. The data bytes are written in the memory location addressed in the EEA byte (A0 to A7) and the CSW byte (A8 to A9 or A10). The programming procedure consists of an internally timed erase/write cycle. In the first step, the selected byte is erased to "1". With the next internal step, the addressed byte is written according to the contents of the buffer.

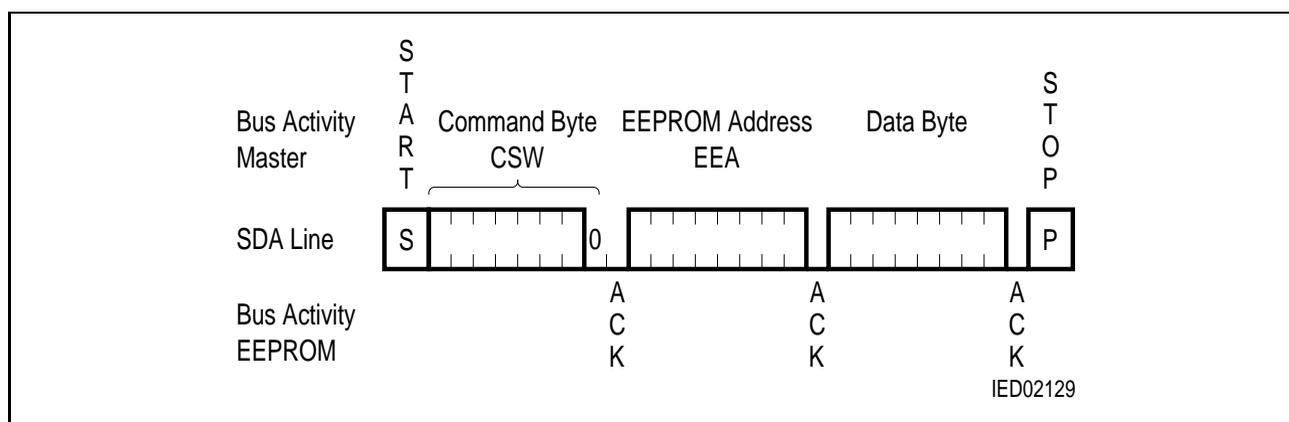

Figure 7
Byte Write Sequence

The erase/write cycle is finished latest after 8 ms. Acknowledge polling may be used for speed enhancement in order to indicate the end of the erase/write cycle (refer to **chapter 5.3** Acknowledge Polling).

5.2 Page Write

Address Setting   The page write procedure is the same as the byte write procedure up to the first data byte. In a page write instruction however, entry of the EEPROM address byte EEA is followed by a sequence of one to maximum sixteen data bytes with the new data to be programmed. These bytes are transferred to the internal page buffer of the EEPROM.

Transmission of Data   The first entered data byte will be stored according to the EEPROM address n given by EEA (A0 to A7) and CSW (A8 to A9 or A10). The internal address counter is incremented automatically after the entered data byte has been acknowledged. The next data byte is then stored at the next higher EEPROM address. EEPROM addresses within the same page have common page address bits A4 through A10. Only the respective four least significant address bits A0 through A3 are incremented, as all data bytes to be programmed simultaneously have to be within the same page.

Programming Cycle   The master stops data entry by applying a STOP condition, which also starts the internally timed erase/write cycle. In the first step, all selected bytes are erased to "1". With the next internal step, the addressed bytes are written according to the contents of the page buffer.

Those bytes of the page that have not been addressed are not included in the programming.
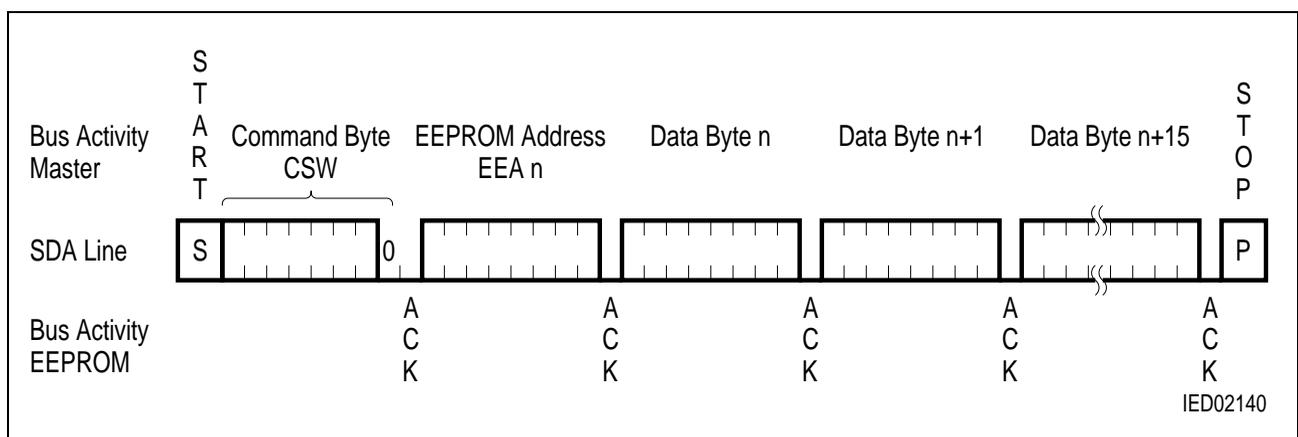

Figure 8
Page Write Sequence

The erase/write cycle is finished latest after 8 ms. Acknowledge polling may be used for speed enhancement in order to indicate the end of the erase/write cycle (refer to **chapter 5.3** Acknowledge Polling).

5.3 Acknowledge Polling

During the erase/write cycle the EEPROM will not respond to a new command byte until the internal write procedure is completed. At the end of active programming the chip returns to the standby mode and the last entered EEPROM byte remains addressed by the address counter. To determine the end of the internal erase/write cycle acknowledge polling can be initiated by the master by sending a START condition followed by a command byte CSR or CSW (read with b0 = 1 or write with b0 = 0). If the internal erase/write cycle is not completed, the device will not acknowledge the transmission. If the internal erase/write cycle is completed, the device acknowledges the received command byte and the protocol activities can continue.
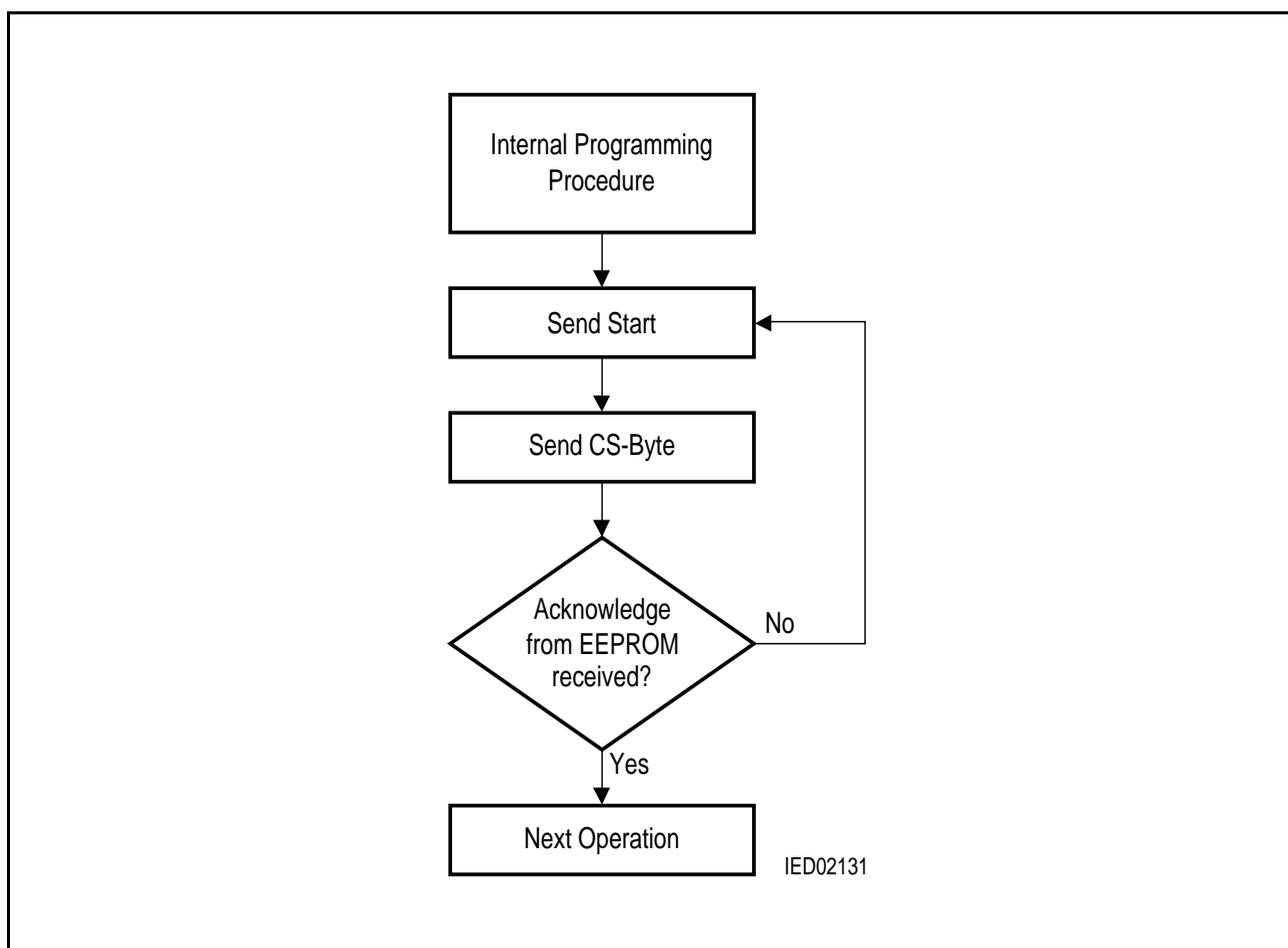

Figure 9
Flow Chart "Acknowledge Polling"
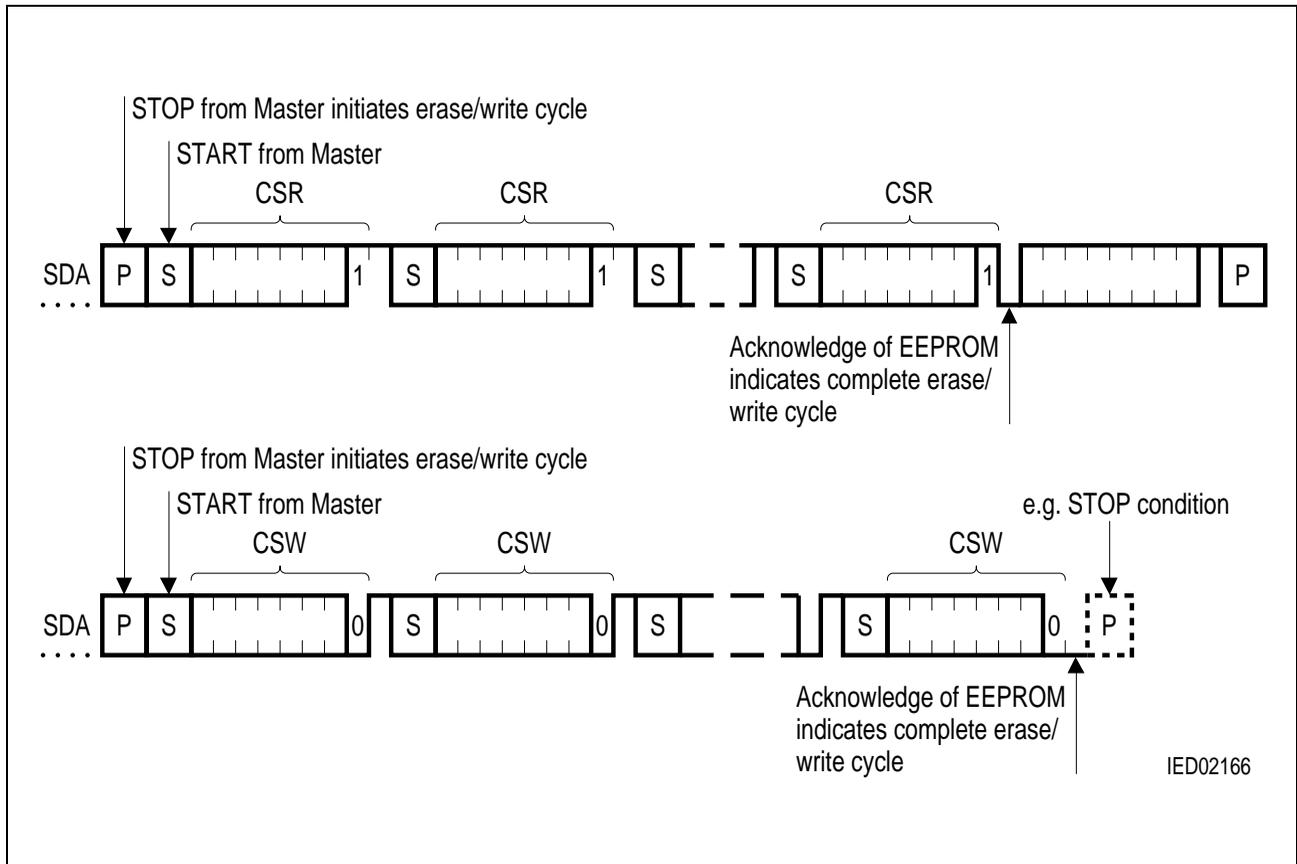

Figure 10
Principle of Acknowledge Polling

6   Read Operations

Reading of the EEPROM data is initiated by the Master with the command byte CSR.

6.1   Random Read

Random read operations allow the master to access any memory location.

Address Setting	The master generates a START condition followed by the command byte CSW. The receipt of the CSW-byte is acknowledged by the EEPROM with a low on the SDA line. Now the master transmits the EEPROM address (EEA) to the EEPROM and the internal address counter is loaded with the desired address.
Transmission of CSR	After the acknowledge for the EEPROM address is received, the master generates a START condition, which terminates the initiated write operation. Then the master transmits the command byte CSR for read, which is acknowledged by the EEPROM.
Transmission of EEPROM Data	During the next eight clock pulses the EEPROM transmits the data byte and increments the internal address counter.
STOP Condition from Master	During the following clock cycle the masters releases the bus and then transmits the STOP condition.
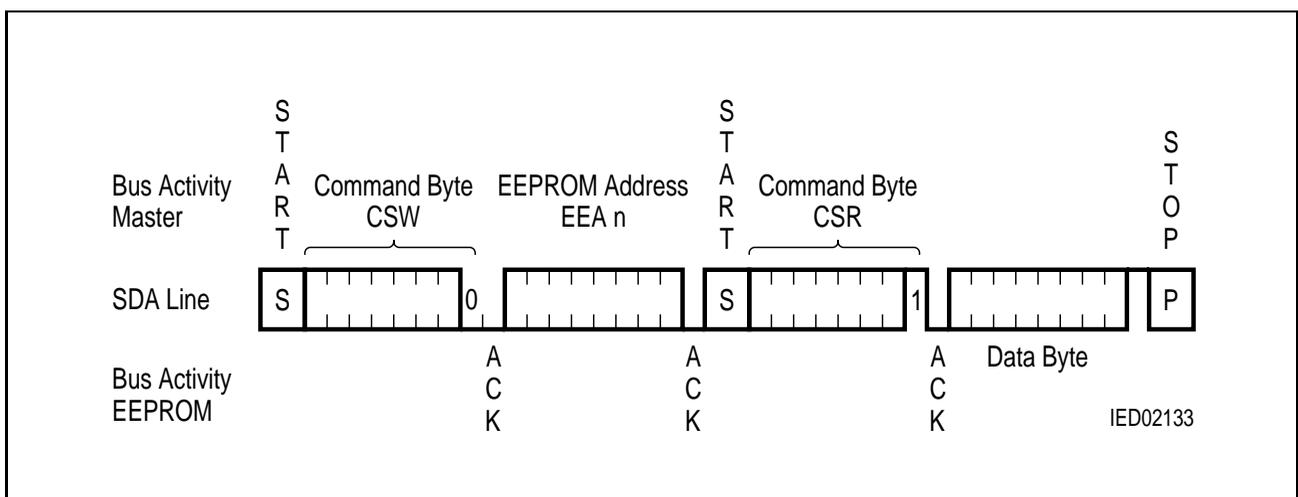

Figure 11
Random Read

6.2   Current Address Read

The EEPROM content is read without setting an EEPROM address, in this case the current content of the address counter will be used (e.g. to continue a previous read operation after the Master has served an interrupt).

|	
Transmission of CSR	For a current address read the master generates a START condition, which is followed by the command byte CSR (chip select read). The receipt of the CSR-byte is acknowledged by the EEPROM with a low on the SDA line.
Transmission of EEPROM Data	During the next eight clock pulses the EEPROM transmits the data byte and increments the internal address counter.
STOP Condition from Master	During the following clock cycle the masters releases the bus and then transmits the STOP condition.
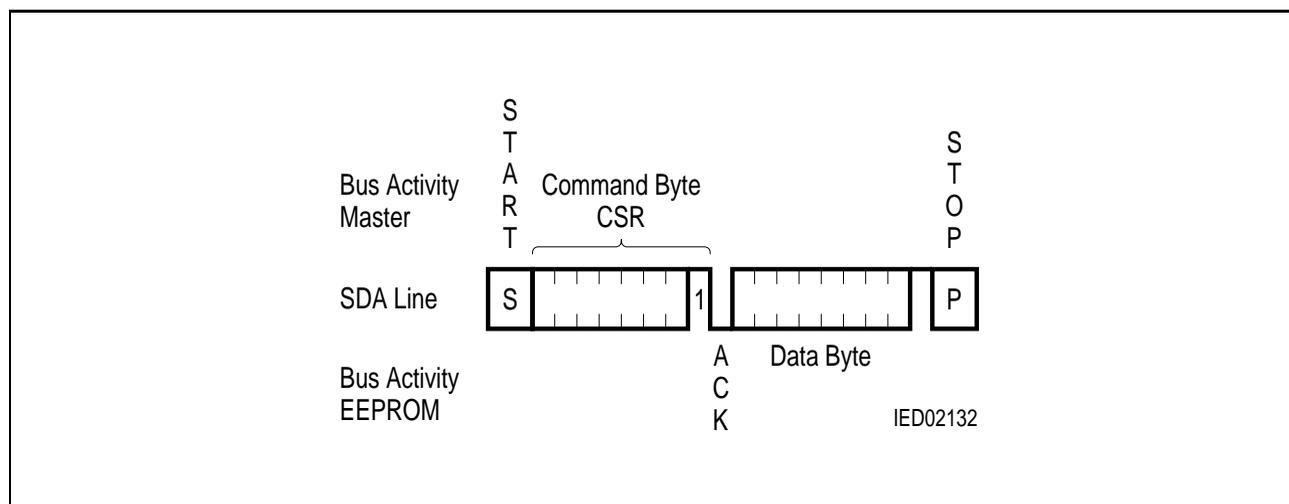

Figure 12
Current Address Read

6.3 Sequential Read

A sequential read is initiated in the same way as a current read or a random read except that the master acknowledges the data byte transmitted by the EEPROM. The EEPROM then continues the data transmission. The internal address counter is incremented by one during each data byte transmission.

A sequential read allows the entire memory to be read during one read operation. After the highest addressable memory location is reached, the internal address pointer "rolls over" to the address 0 and the sequential read continues.

The transmission is terminated by the master by releasing the SDA line (no acknowledge) and generating a STOP condition (see **figure 13**).
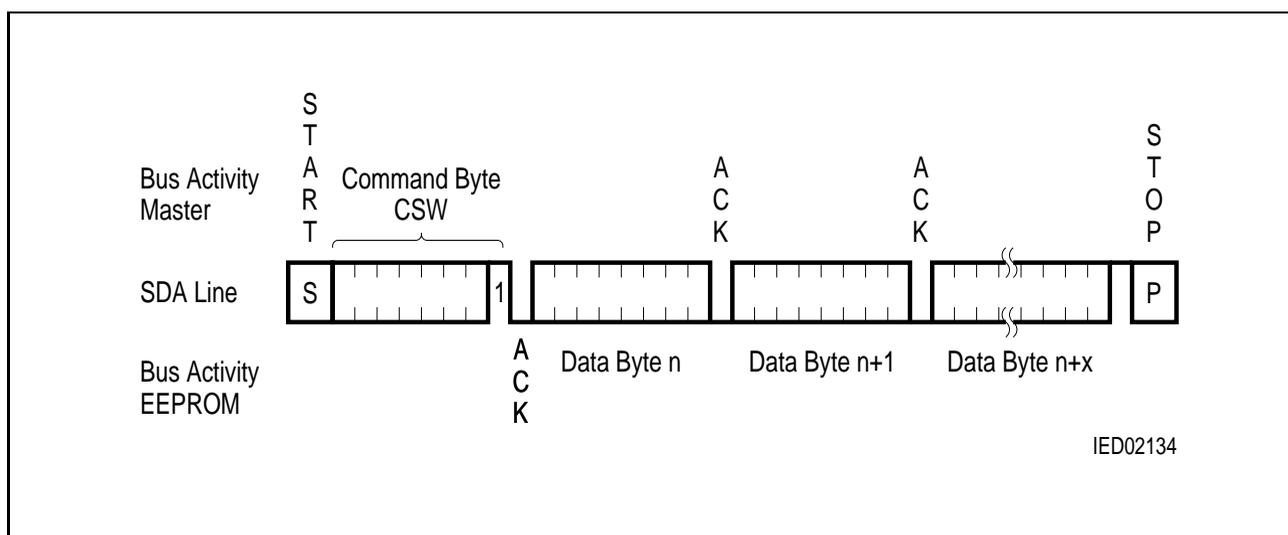

Figure 13
Sequential Read

7 Page Protection Mode™

Each page (16 bytes) in the Data Memory can be protected against unintended data changes by an associated protection bit. The protection bit memory consists of an additional EEPROM of 64/128 bits (**figure 14**).

Data in the Data Memory can be modified only if the assigned protection bit is erased (logical state "1"). After writing the data bytes to a page, the protection is achieved by writing the associated protection bit (logical state "0"). Further changes in the data in a protected page is possible only after erasing the protection bit.
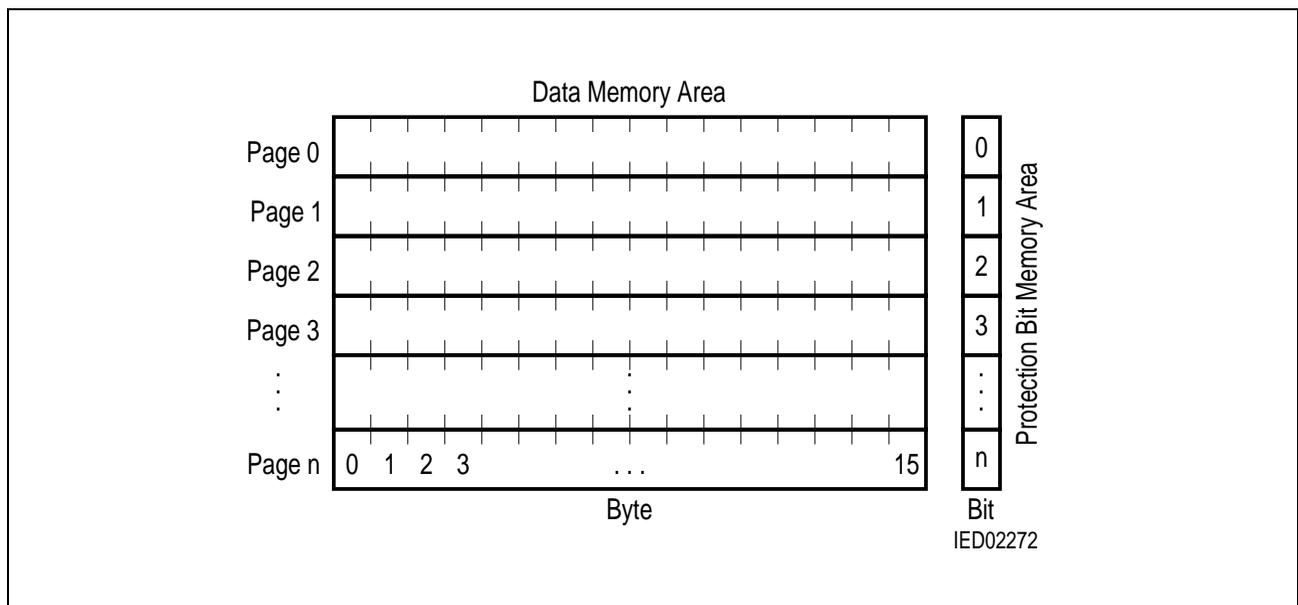

Figure 14
Data Page and Assigned Protection Memory

A special procedure to write or erase a protection bit guarantees proper activation or deactivation respectively of page protection. For protection bit write or erase, all 16 data bytes of the respective page have to be entered for a second time. The data then are compared internally with the data to be protected, and in case of identity the protection bit is written or erased respectively.

7.1 Protection Bit Handling

The bits of the protection memory can be addressed directly for reading or programming. A protection bit address corresponds to the lowest address within the respective page (A4 to A9 or A10, A0 to A3 = zero). The status of each protection bit is sensed internally. A written state ("0") prevents programming in the associated page. If an already protected memory page is accidentally addressed for programming, the programming procedure is suppressed.

The conventional I^2C-Bus protocol allows data bytes to be read and programmed only. Therefore an independent instruction sequence for addressing and manipulation of protection bits is implemented. For protection bit instructions, the command byte CSW with its preceding START condition followed by the associated control byte has to be entered twice (**figures 15** through **17**). The first command byte CSW (with A8 to A9 or A10) is followed by the control byte EEA with the bit/page address A0 through A3 always at zero. The second CSW is required for entering a control byte CTx for protection bit manipulation. The three control bytes for read, write or erase of a protection bit are listed below (**table 3**):

Table 3
Control Byte for Protection Bit Manipulation

Address Name	Definition								Function
	b7	b6	b5	b4	b3	b2	b1	b0	
CTR	x	x	x	x	x	x	0	0	Protection bit read
CTW	x	x	x	x	x	x	0	1	Protection bit write
CTE	x	x	x	x	x	x	1	1	Protection bit erase

SIEMENS

7.2 Protection Bit Write and Erase

For writing or erasing a protection bit, the data of the respective page have to be known by the master. The data of the page are not affected by the write or erase procedure of the protection bit. The I^{2}C-Bus protocol is shown in **figure 15** for protection bit write and **figure 16** for protection bit erase.
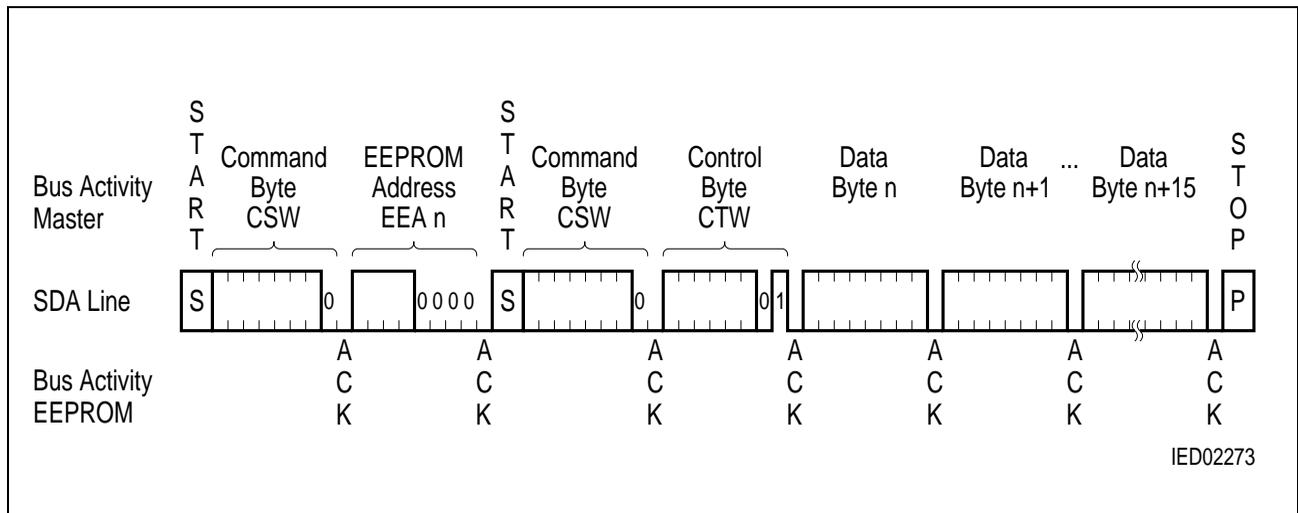

Figure 15
Sequence for Protection Bit Write
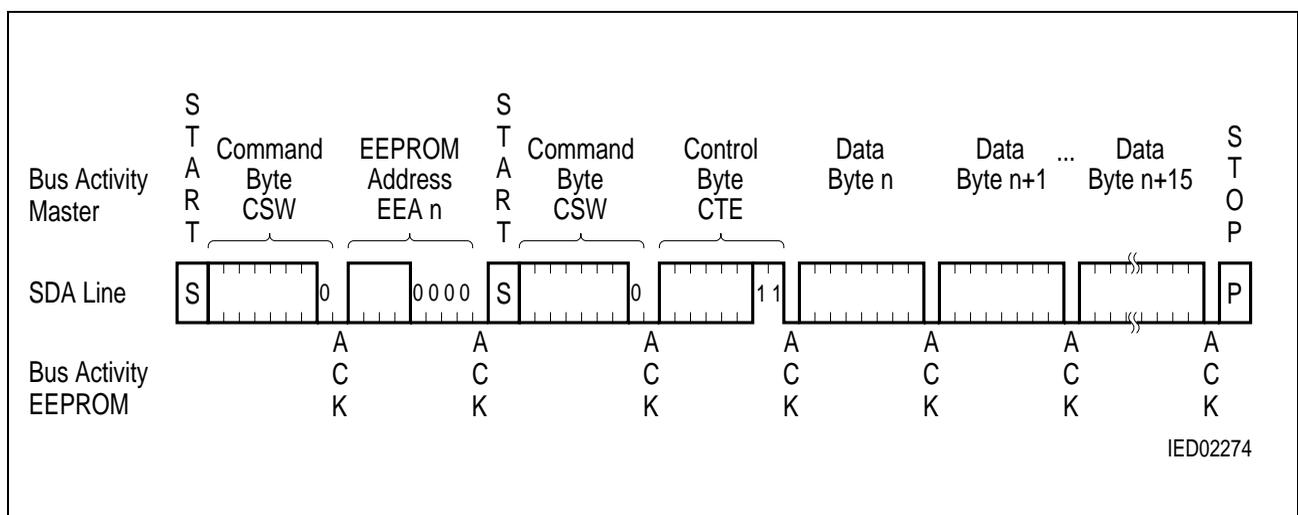

Figure 16
Sequence for Protection Bit Erase

The first command byte CSW followed by the control byte EEA addresses the page to be protected. The second command byte CSW (identical content of first CSW) is followed by the control byte CTW = 01$_H$ for protection bit write or CTE = 03$_H$ for protection bit erase. Depending on CTx, the addressed protection bit will be either written or erased.

The control byte CTx is followed by 16 parameter bytes identical to the 16 data bytes of the page to be protected or unprotected. The data of the first entered byte must be identical to the data byte stored at the lowest address of the current page. The other 15 bytes have to be identical to the bytes stored in ascending address order within the same page.

A successful verification of each byte is indicated by the EEPROM by pulling the SDA line to low (acknowledge ACK).

After verification of the last byte, the bit programming procedure is initiated by the STOP condition. Programming is started only if all 128 bits of a page have been verified successfully. If bit programming has taken place, the address counter points to the uppermost address of the respective page. The write or erase cycle is finished latest after 4 ms. Acknowledge polling may be used for speed enhancement in order to indicate the end of the write or erase cycle (refer to **chapter 5.3** Acknowledge Polling).

7.3 Protection Bit Read

The byte sequence for random bit read is shown in **figure 17**.

**Figure 17**
Byte Sequence for Protection Bit Read

The first command byte CSW followed by the control byte EEA addresses the protection bit to be read. The second command byte CSW is followed by the control byte 00_H for protection bit read. The first bit (MSB) of the transferred byte is the protection bit of the addressed page. The other 7 bits are not valid. The page protection status is indicated as following
Protection Bit = 1: A normal write operation changes the data in the associated page
Protection Bit = 0: The data in the associated page are protected against changes.

If the master acknowledges a byte with a low state of the SDA line, the protection bit of the next page can be read as the first bit of the following byte. If the master releases the SDA line, a STOP condition has to complete the read procedure. Any number of bytes with a page protection status at the first bit position can be requested by the master. If the bit of the uppermost page has been addressed, the counter has its overflow to the lowest address according to the first page.

8 Electrical Characteristics

The listed characteristics are ensured over the operating range of the integrated circuit. Typical characteristics specify mean values expected over the production spread. If not otherwise specified, typical characteristics apply at T_A = 25 °C and the given supply voltage.

8.1 Absolute Maximum Ratings

Stresses above those listed here may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this data sheet is not implied. Exposure to absolute maximum ratings for extended periods may affect device reliability.

Parameter		Limit Values	Units
Operating temperature	range 1 (industrial)	– 40 to + 85	°C
	range 2 (automotive)	– 40 to + 125	°C
Storage temperature		– 65 to + 150	°C
Supply voltage		– 0.3 to + 7.0	V
All inputs and outputs with respect to ground		– 0.3 to V_{CC} + 0.5	V
ESD protection (human body model)		4000	V

8.2 DC Characteristics

Parameter	Symbol	Limit Values			Units	Test Condition
		min.	typ.	max.		
Supply voltage	V_{CC}	4.5		5.5	V	5 V type
	V_{CC}	2.7		5.5	V	3 V type
Supply current[1] (write)	I_{CC}		1	3	mA	V_{CC} = 5 V; f_c = 100 kHz
Standby current[2]	I_{SB}			50	µA	Inputs at V_{CC} or V_{SS}
Input leakage current	I_{LI}		0.1	10	µA	V_{IN} = V_{CC} or V_{SS}
Output leakage current	I_{LO}		0.1	10	µA	V_{OUT} = V_{CC} or V_{SS}
Input low voltage	V_{IL}	– 0.3		$0.3 \times V_{CC}$	V	

8.2 DC Characteristics (cont'd)

Parameter	Symbol	Limit Values			Units	Test Condition
		min.	**typ.**	**max.**		
Input high voltage	V_{IH}	$0.7 \times V_{CC}$		$V_{CC} + 0.5$	V	
Output low voltage	V_{OL}			0.4	V	$I_{OL} = 3$ mA; $V_{CC} = 5$ V $I_{OL} = 2.1$ mA; $V_{CC} = 3$ V
Input/output capacitance (SDA)	$C_{I/O}$			$8^{3)}$	pF	$V_{IN} = 0$ V; $V_{CC} = 5$ V
Input capacitance (other pins)	C_{IN}			$6^{3)}$	pF	$V_{IN} = 0$ V; $V_{CC} = 5$ V
Capacitive load for each bus line	C_b			400	pF	

[1] The values for I_{cc} are maximum peak values

[2] Valid over the whole temperature range

[3] This parameter is characterized only

8.3 AC Characteristics

Parameter	Symbol	Limit Values V_{CC} = 2.7-5.5 V		Limit Values V_{CC} = 4.5-5.5 V		Units
		min.	max.	min.	max.	
SCL clock frequency	f_{SCL}		100		400	kHz
Clock pulse width low	t_{low}	4.7		1.2		µs
Clock pulse width high	t_{high}	4.0		0.6		µs
SDA and SCL rise time	t_R		1000	1)	300	ns
SDA and SCL fall time	t_F		300	1)	300	ns
Start set-up time	$t_{SU.STA}$	4.7		0.6		µs
Start hold time	$t_{HD.STA}$	4.0		0.6		µs
Data in set-up time	$t_{SU.DAT}$	200		100		ns
Data in hold time	$t_{HD.DAT}$	0		0		µs
SCL low to SDA data out valid	t_{AA}	0.1	4.5	0.1	0.9	µs
Data out hold time	t_{DH}	100		50		ns
Stop set-up time	$t_{SU.STO}$	4.0		0.6		µs
Time the bus must be free before a new transmission can start	t_{BUF}	4.7		1.2		µs
SDA and SCL spike suppression time at constant inputs	t_I	50	100	50	100	ns

1) The minimum rise and fall times can be calculated as follows: $20 + (0.1/pF) \times C_b$ [ns]
   Example: C_b = 100 pF $\rightarrow t_R = 20 + 0.1 \times 100$ [ns] = 30 ns

8.4 Erase and Write Characteristics

Parameter	Symbol	Limit Values V_{CC} = 2.7-5.5 V		Limit Values V_{CC} = 4.5-5.5 V		Units
		typ.	max.	typ.	max.	
Erase + write cycle (per page)	t_{WR}	5	8	5	8	ms
Erase page protection bit		2.5	4	2.5	4	ms
Write page protection bit		2.5	4	2.5	4	ms
