## description

The TLV5580 is an 8-bit 80 MSPS high-speed A/D converter. It converts the analog input signal into 8-bit binary-coded digital words up to a sampling rate of 80 MHz . All digital inputs and outputs are 3.3 V TTL/CMOS-compatible.
The device consumes very little power due to the 3.3 V supply and an innovative single-pipeline architecture implemented in a CMOS process. The user obtains maximum flexibility by setting both bottom and top voltage references from user-supplied voltages. If no external references are available, on-chip references are available for internal and external use. The full-scale range is 1 Vpp up to 1.6 Vpp , depending on the analog supply voltage. If external references are available, the internal references can be disabled independently from the rest of the chip, resulting in an even greater power saving.
While usable in a wide variety of applications, the device is specifically suited for the digitizing of high-speed graphics and for interfacing to LCD panels or LCD/DMD projection modules. Other applications include DVD read channel digitization, medical imaging and communications. This device is suitable for IF sampling of communication systems using sub-Nyquist sampling methods because of its high analog input bandwidth.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

## functional block diagram

The single-pipeline architecture uses 6 ADC/DAC stages and one final flash ADC. Each stage produces a resolution of 2 bits. The correction logic generates its result using the 2-bit result from the first stage, 1 bit from each of the 5 succeeding stages, and 1 bit from the final stage in order to arrive at an 8 -bit result. The correction logic guarantees no missing codes over the full operating temperature range.

## TLV5580

8-BIT, 80 MSPS LOW-POWER A/D CONVERTER

Terminal Functions

| TERMINAL |  |  |  |
| :---: | :---: | :---: | :---: |
| NAME | NO. | 1/0 | DESCRIPTION |
| AIN | 26 | 1 | Analog input |
| $A V_{\text {DD }}$ | 16, 27 | 1 | Analog supply voltage |
| AVSS | 18, 23, 28 | 1 | Analog ground |
| BG | 17 | O | Band gap reference voltage. A $1 \mu \mathrm{~F}$ capacitor (with an optional $0.1 \mu \mathrm{~F}$ capacitor in parallel) should be connected between this terminal and $\mathrm{AV}_{\mathrm{SS}}$ for external filtering. |
| CLK | 12 | 1 | Clock input. The input is sampled on each rising edge of CLK. |
| CML | 25 | O | Common mode level. This voltage is equal to ( $\left.\mathrm{AV}_{\mathrm{DD}}-\mathrm{AV}_{\mathrm{SS}}\right) \div 2$. An external $0.1 \mu \mathrm{~F}$ capacitor should be connected between this terminal and AV SS. |
| D0 - D7 | 2-9 | 0 | Data outputs. D7 is the MSB |
| DRV ${ }_{\text {DD }}$ | 1 | 1 | Supply voltage for digital output drivers |
| $\mathrm{DRV}_{\text {SS }}$ | 10 | 1 | Ground for digital output drivers |
| DVDD | 14 | 1 | Digital supply voltage |
| $\overline{\mathrm{OE}}$ | 13 | 1 | Output enable. When high the D0 - D7 outputs go in high-impedance mode. |
| DV ${ }_{\text {SS }}$ | 11 | 1 | Digital ground |
| PWDN_REF | 24 | I | Power down for internal reference voltages. A high on this terminal will disable the internal reference circuit. |
| REFBI | 21 | I | Reference voltage bottom input. The voltage at this terminal defines the bottom reference voltage for the ADC. It can be connected to REFBO or to an externally generated reference level. Sufficient filtering should be applied to this input. The use a $0.1 \mu \mathrm{~F}$ capacitor connected between REFBI and AVSS is recommended. Additionaly, a $0.1 \mu \mathrm{~F}$ capacitor can be connected between REFTI and REFBI. |
| REFBO | 22 | 0 | Reference voltage bottom output. An internally generated reference is available at this terminal. It can be connected to REFBI or left unconnected. A $1 \mu \mathrm{~F}$ capacitor between REFBO and $A V_{S S}$ will provide sufficient decoupling required for this output. |
| REFTI | 20 | I | Reference voltage top input. The voltage at this terminal defines the top reference voltage for the ADC. It can be connected to REFTO or to an externally generated reference level. Sufficient filtering should be applied to this input. The use of a $0.1 \mu$ F capacitor between REFTI and $\mathrm{AV}_{\mathrm{SS}}$ is recommended. Additionaly, a $0.1 \mu \mathrm{~F}$ capacitor can be connected between REFTI and REFBI. |
| REFTO | 19 | 0 | Reference voltage top output. An internally generated reference is available at this terminal. It can be connected to REFTI or left unconnected. A $1 \mu \mathrm{~F}$ capacitor between REFTO and $\mathrm{AV}_{\text {SS }}$ will provide sufficient decoupling required for this output. |
| STBY | 15 | 1 | Standby input. A high level on this input enables a powerdown mode. |

| Full scale error |  |  |  |  | 5 | \%FS |

NOTES: 1. Integral nonlinearity refers to the deviation of each individual code from a line drawn from zero to full scale. The point used as zero occurs $1 / 2$ LSB before the first code transition. The full-scale point is defined as a level $1 / 2$ LSB beyond the last code transition. The deviation is measured from the center of each particular code to the true straight line between these two endpoints.
2. An ideal ADC exhibits code transitions that are exactly 1 LSB apart. DNL is the deviation from this ideal value. Therefore this measure indicates how uniform the transfer function step sizes are. The ideal step size is defined here as the step size for the device under test (i.e., (last transition level - first transition level) $\div\left(2^{n}-2\right)$ ). Using this definition for DNL separates the effects of gain and offset error. A minimum DNL better than -1 LSB ensures no missing codes.
3. Zero error is defined as the difference in analog input voltage - between the ideal voltage and the actual voltage - that will switch the ADC output from code 0 to code 1. The ideal voltage level is determined by adding the voltage corresponding to $1 / 2$ LSB to the bottom reference level. The voltage corresponding to 1 LSB is found from the difference of top and bottom references divided by the number of ADC output levels (256).
Full-scale error is defined as the difference in analog input voltage - between the ideal voltage and the actual voltage - that will switch the ADC output from code 254 to code 255 . The ideal voltage level is determined by subtracting the voltage corresponding to 1.5 LSB from the top reference level. The voltage corresponding to 1 LSB is found from the difference of top and bottom references divided by the number of ADC output levels (256).

| th(o) | Output hold time | $\mathrm{C}_{\mathrm{L}}=2 \mathrm{pF}$, | See Note 5 | 2 |  |  | ns |
| $\mathrm{t}_{\mathrm{d} \text { (pipe) }}$ | Pipeline delay (latency) | See Note 6 |  | 4.5 | 4.5 | 4.5 | CLK <br> cycles |
| $\mathrm{t}_{\mathrm{d}}(\mathrm{a})$ | Aperture delay time | See Note 5 |  |  | 3 |  | ns |
| $\mathrm{t}_{\mathrm{j}}(\mathrm{a})$ | Aperture jitter |  |  |  | 1.5 |  | ps, rms |
| $\mathrm{t}_{\text {dis }}$ | Disable time, $\overline{\mathrm{OE}}$ rising to $\mathrm{Hi}-\mathrm{Z}$ |  |  |  | 5 | 8 | ns |
| $t_{\text {en }}$ | Enable, $\overline{\mathrm{OE}}$ falling to valid data |  |  |  | 5 | 8 | ns |

NOTES: 5. Output timing $\mathrm{t}_{\mathrm{d}(0)}$ is measured from the 1.5 V level of the CLK input falling edge to the $10 \% / 90 \%$ level of the digital output. The digital output load is not higher than 10 pF .
Output hold time $\mathrm{th}_{\mathrm{h}}(\mathrm{o})$ is measured from the 1.5 V level of the CLK input falling edge to the $10 \% / 90 \%$ level of the digital output. The digital output is load is not less than 2 pF .
Aperture delay $\mathrm{t}_{\mathrm{d}}(\mathrm{A})$ is measured from the 1.5 V level of the CLK input to the actual sampling instant.
The OE signal is asynchronous.
OE timing $t_{d i s}$ is measured from the $V_{I H}(M I N)$ level of $O E$ to the high-impedance state of the output data. The digital output load is not higher than 10 pF .
OE timing $t_{\text {en }}$ is measured from the $\mathrm{V}_{\mathrm{IL}(\mathrm{MAX})}$ level of OE to the instant when the output data reaches $\mathrm{V}_{\mathrm{OH}(\mathrm{min})}$ or $\mathrm{V}_{\mathrm{OL}(\max )}$ output levels. The digital output load is not higher than 10 pF .
6. The number of clock cycles between conversion initiation on an input sample and the corresponding output data being made available from the ADC pipeline. Once the data pipeline is full, new valid output data is provided on every clock cycle. In order to know when data is stable on the output pins, the output delay time $t_{d}(0)$ (i.e., the delay time through the digital output buffers) needs to be added to the pipeline latency. Note that since the max. $\mathrm{t}_{\mathrm{d}(\mathrm{o})}$ is more than $1 / 2$ clock period at 80 MHz ; data cannot be reliably clocked in on a rising edge of CLK at this speed. The falling edge should be used.

## PRINCIPLE OF OPERATION

The TLV5580 implements a high-speed 80 Msps converter in a cost-effective CMOS process. Powered from 3.3 V , the single-pipeline design architecture ensures low-power operation and 8 bit accuracy. Signal input and clock signals are all single-ended. The digital inputs are 3.3 V TTL/CMOS compatible. Internal voltage references are included for both bottom and top voltages. Therefore the converter forms a self-contained solution. Alternatively the user may apply externally generated reference voltages. In doing so, both input offset and input range can be modified to suit the application.
A high-speed sampling-and-hold captures the analog input signal. Multiple stages will generate the output code with a pipeline delay of 4.5 CLK cycles. Correction logic combines the multistage data and aligns the 8 -bit output word. All digital logic operates at the rising edge of CLK.

## analog input

Figure 12. Simplified Equivalent Input Circuit
A first-order approximation for the equivalent analog input circuit of the TLV5580 is shown in Figure 12. The equivalent input capacitance $\mathrm{C}_{\text {| }}$ is 4 pF typical. The input must charge/discharge this capacitance within the sample period of one half clock cycle. When a full-scale voltage step is applied, the input source provides the charging current through the switch resistance $R_{\text {SW }}(200 \Omega)$ of S1 and quickly settles. In this case the input impedance is low. Alternatively, when the source voltage equals the value previously stored on $\mathrm{C}_{\boldsymbol{l}}$, the hold capacitor requires no input current and the equivalent input impedance is very high.
To maintain the frequency performance outlined in the specifications, the total source impedance should be limited to about $80 \Omega$, as follows from the equation with $\mathrm{f}_{\mathrm{CLK}}=80 \mathrm{MHz}, \mathrm{C}_{\mathrm{l}}=4 \mathrm{pF}, \mathrm{R}_{\mathrm{SW}}=200 \Omega$ :

$$
R_{S}<\left[1 \div\left(2{ }^{f} C_{C L K} \times C_{I} \times \ln (256)\right)-R_{S W}\right]
$$

So, for applications running at a lower ${ }^{\mathrm{f}}$ CLK, the total source resistance can increase proportionally.

## PRINCIPLE OF OPERATION

## dc coupled input

(a)

(b)

Figure 13. DC-Coupled Input Circuit
For dc-coupled systems an opamp can level-shift a ground-referenced input signal. A circuit as shown in Figure 13(a) is acceptable. Alternatively, the user might want a bipolar shift together with the bottom reference voltage as seen in Figure 13(b). In this case the AIN voltage is given by:

$$
\mathrm{AIN}=2 \times R_{2} \div\left(R_{1}+R_{2}\right) \times V_{R E F}-V_{I N}
$$

## ac coupled input

Figure 14. AC-Coupled Input Circuit
For many applications, especially in single supply operation, ac coupling offers a convenient way for biasing the analog input signal at the proper signal range. Figure 14 shows a typical configuration. To maintain the outlined specifications, the component values need to be carefully selected. The most important issue is the positioning of the 3 dB high-pass corner point $f_{-3} \mathrm{~dB}$, which is a function of $R_{2}$ and the parallel combination of $\mathrm{C}_{1}$ and $\mathrm{C}_{2}$, called $\mathrm{C}_{\mathrm{eq}}$. This is given by the following equation:

$$
f_{-3 d B}=1 \div\left(2 \pi \times R_{2} \times C_{e q}\right)
$$

where $\mathrm{C}_{\mathrm{eq}}$ is the parallel combination of $\mathrm{C}_{1}$ and $\mathrm{C}_{2}$.
Since C1 is typically a large electrolytic or tantalum capacitor, the impedance becomes inductive at higher frequencies. Adding a small ceramic or polystyrene capacitor, C 2 of approximately $0.01 \mu \mathrm{~F}$, which is not inductive within the frequency range of interest, maintains low impedance. If the minimum expected input signal frequency is 20 kHz , and $R 2$ equals $1 \mathrm{k} \Omega$ and $R 1$ equals $50 \Omega$, the parallel capacitance of C 1 and C 2 must be a minimum of 8 nF to avoid attenuating signals close to 20 kHz .

## PRINCIPLE OF OPERATION

## reference terminals

The voltages on terminals REFBI and REFTI determine the TLV5580's input range. Since the device has an internal voltage reference generator with outputs available on REFBO respectively REFTO, corresponding terminals can be directly connected externally to provide a contained ADC solution. Especially at higher sampling rates, it is advantageous to have a wider analog input range. The wider analog input range is achievable by using external voltage references (e.g., at AVDD $=3.3 \mathrm{~V}$, the full scale range can be extended from 1 Vpp (internal reference) to 1.3 Vpp (external reference) as shown in Table 1). These voltages should not be derived via a voltage divider from a power supply source. Instead, use a bandgap-derived voltage reference to derive both references via an opamp circuit. Refer to the schematic of the TLV5580 evaluation module for an example circuit.

When using external references, the full-scale ADC input range and its dc position can be adjusted. The full-scale $A D C$ range is always equal to $\mathrm{V}_{\text {REFT }}-\mathrm{V}_{\text {REFB }}$. The maximum full-scale range is dependent on $A V_{D D}$ as shown in the specification section. In addition to the limitation on their difference, $\mathrm{V}_{\text {REFT }}$ and $\mathrm{V}_{\text {REFB }}$ each also have limits on their useful range. These limits are also dependent on $A V_{D D}$.

Table 3 summarizes these limits for 3 cases.
Table 1. Recommended Operating Modes

| $\mathbf{A V} \mathbf{D D}$ | $\mathrm{V}_{\text {REFB(min) }}$ | $\mathrm{V}_{\text {REFB(max) }}$ | $\mathrm{V}_{\text {REFT(min) }}$ | $\mathrm{V}_{\text {REFT(max) }}$ | $\left[\mathrm{V}_{\text {REFT }} \mathrm{V}_{\text {REFB }}\right]_{\max }$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 3 V | 0.8 V | 1.2 V | 1.8 V | 2.2 V | 1 V |
| 3.3 V | 0.8 V | 1.2 V | 2.1 V | 2.5 V | 1.3 V |
| 3.6 V | 0.8 V | 1.2 V | 2.4 V | 2.8 V | 1.6 V |

## digital inputs

The digital inputs are CLK, STDBY, PWDN_REF, and OE. All these signals, except CLK, have an internal pull-down resistor to connect to digital ground. This provides a default active operation mode using internal references when left unconnected.

The CLK signal at high frequencies should be considered as an analog input. Overshoot/undershoot should be minimized by proper termination of the signal close to the TLV5580. An important cause of performance degradation for a high-speed ADC is clock jitter. Clock jitter causes uncertainty in the sampling instant of the ADC, in addition to the inherent uncertainty on the sampling instant caused by the part itself, as specified by its aperture jitter. There is a theoretical relationship between the frequency (f) and resolution ( 2 N ) of a signal that needs to be sampled and the maximum amount of aperture error $\mathrm{dt}_{\mathrm{max}}$ that is tolerable. The following formula shows the relation:

$$
d t_{\max }=1 \div\left[\pi f 2^{(N+1)}\right]
$$

As an example, for an 8-bit converter with a $15-\mathrm{MHz}$ input, the jitter needs to be kept $<41 \mathrm{pF}$ in order not to have changes in the LSB of the ADC output due to the total aperture error.

## PRINCIPLE OF OPERATION

## digital outputs

The output of TLV5580 is a standard binary code. Capacitive loading on the output should be kept as low as possible (a maximum loading of 10 pF is recommended) to provide best performance. Higher output loading causes higher dynamic output currents and can increase noise coupling into the device's analog front end. To drive higher loads, use an output buffer is recommended.

When clocking output data from TLV5580, it is important to observe its timing relation to CLK. Pipeline ADC delay is 4.5 clock cycles to which the maximum output propagation delay is added. See Note 6 in the specification section for more details.

## layout, decoupling and grounding rules

It is necessary for any PCB using the TLV5580 to have proper grounding and layout to achieve the stated performance. Separate analog and digital ground planes that are spliced underneath the device are advisable. TLV5580 has digital and analog terminals on opposite sides of the package to make proper grounding easier. Since there is no internal connection between analog and digital grounds, they have to be joined on the PCB. Joining the digital and analog grounds at a point in close proximity to the TLV5580 is advised.

As for power supplies, separate analog and digital supply terminals are provided on the device ( $\mathrm{AV} \mathrm{V}_{\mathrm{DD}} / \mathrm{DV}_{\mathrm{DD}}$ ). The supply to the digital output drivers is kept separate also ( $\mathrm{DRV} \mathrm{DD}_{\mathrm{D}}$ ). Lowering the voltage on this supply from the nominal 3.3 V to 3 V improves performance because of the lower switching noise caused by the output buffers.

Due to the high sampling rate and switched-capacitor architecture, TLV5580 generates transients on the supply and reference lines. Proper decoupling of these lines is essential. Decoupling as shown in the schematic of the TLV5580 EVM is recommended.

## TLV5580 EVALUATION MODULE

## TLV5580 evaluation module

TI provides an evaluation module (EVM) for TLV5580. The EVM also includes a 10 b 80 MSPS DAC so that the user can convert the digitized signal back to the analog domain for functional testing. Performance measurements can be done by capturing the ADC's output data.
The EVM provides the following additional features:

- Provision of footprint for the connection of an onboard crystal oscillator, instead of using an external clock input.
- Use of TLV5580 internal or external voltage references. In the case of external references, an onboard circuit is used that derives adjustable bottom and top reference voltages from a bandgap reference. Two potentiometers allow for the independent adjustments of both references. The full scale ADC range can be adjusted to the input signal amplitude.
- All digital output, control signal I/O (output enable, standby, reference powerdown) and clock I/O are provided on a single connector. The EVM can thus be part of a larger (DSP) system for prototyping.
- Onboard prototyping area with analog and digital supply and ground connections.

Figure 15 shows the EVM schematic.
The EVM is factory shipped for use in the following configuration:

- Use of external (onboard) voltage references
- External clock input

## analog input

A signal in the range between $\mathrm{V}_{(\text {REFBI }}$ and $\mathrm{V}_{(\text {REFTI }}$ should be applied to avoid overflow/underflow on connector J 10 . This signal is onboard terminated with $50 \Omega$. There is no onboard biasing of the signal. When using external (onboard) references, these levels can be adjusted with R7 ( $\mathrm{V}_{\text {(REFTI) }}$ ) and R6 ( $\mathrm{V}_{\text {(REFBI) }}$ ). Adjusting R7 causes both references to shift. R6 only impacts the bottom reference. The range of these signals for which the device is specified depends on $\mathrm{AV}_{\mathrm{DD}}$ and is shown under the Recommended Operating Conditions.
Internally generated reference levels are also dependent on $A V_{D D}$ as shown in the electrical characteristics section.

## clock input

A clock signal should be applied with amplitudes ranging from 0 to $A V_{D D}$ with a frequency equal to the desired sampling frequency on connector J 9 . This signal is onboard terminated with $50 \Omega$. Both ADC and DAC run off the same clock signal. Alternatively the clock can be applied from terminal 1 on connector J11. A third option is using a crystal oscillator. The EVM board provides the footprint for a crystal oscillator that can be populated by the end-user, depending on the desired frequency. The footprint is compatible with the Epson EG-8002DC series of programmable high-frequency crystal oscillators. Refer to the TLV5580 EVM Settings for selecting between the different clock modes.

## TLV5580 EVALUATION MODULE

## power supplies

The board provides seven power supply connectors (see Table 2). For optimum performance, analog and digital supplies should be kept separate. Using separate supplies for the digital logic portion of TLV5580 (DV ${ }_{\text {DD }}$ ) and its output drivers $\left(D R V_{D D}\right)$ benefits dynamic performance, especially when $D R V_{D D}$ is put at the minimum required voltage ( 3 V ), while $\mathrm{DV}_{\mathrm{DD}}$ might be higher (up to 3.6 V ). This lowers the switching noise on the die caused by the output drivers.

Table 2. Power Supplies

| SIGNAL <br> NAME | CONNECTOR | BOARD <br> LABEL | DESCRIPTION |
| :---: | :---: | :---: | :--- |
| DRV3 | J 1 | 3DRV | 3.3 V digital supply for TLV5580 (digital output drivers) |
| DV3 | J 2 | 3 VD | 3.3 V digital supply for TLV5580 (digital logic) and peripherals |
| DV5 | J 3 | 5 VD | 5 V digital supply for D/A converter and peripherals |
| AV3 | J 4 | 3 VA | 3.3 V analog supply for TLV5580 |
| AV5 | J 5 | 5 VA | 5 V analog supply for onboard reference circuit and D/A converter. Can be left unconnected if <br> internal references are used and no D/A conversion is required. |
| AV+12 | J6 | 12 VA | 12 V analog supply for onboard reference circuit. Can be left unconnected if internal references <br> are used. |
| AV-12 | J7 | -12 VA | -12 V analog supply for onboard reference circuit. Can be left unconnected if internal <br> references are used. |

## voltage references

SW1 and SW2 switch between internal and external top and bottom references respectively. The external references are onboard generated from a stable bandgap-derived 3.3 V signal (using TI's TPS 7133 and quad-opamp TLE2144). They can be adjusted via potentiometers $\mathrm{R} 6\left(\mathrm{~V}_{(\mathrm{REFBI}}\right)$ and $\mathrm{R} 7\left(\mathrm{~V}_{(\mathrm{REFTI})}\right)$. It is advised to power down the internal voltage references by asserting PWN_REF when onboard references are used.
The references are measured at test points TP3 $\left(\mathrm{V}_{(\text {REFB }}\right)$ and TP4 $\left(\mathrm{V}_{(\text {REFT }}\right)$.

## DAC output

The onboard DAC is a 10-bit 80 MSPS converter. It is connected back-to-back to the TLV5580. While the user could use its analog output for measurements, the DAC output is directly connected to connector J8 and does not pass through an analog reconstruction filter. So mirror spectra from aliased signal components feed through into the analog output.

For this reason and to separate ADC and DAC contributions, performance measurements should be made by capturing the ADC output data available on connector J 11 and not by evaluating the DAC output.

## TLV5580 EVALUATION MODULE

## TLV5580 EVM settings

clock input settings

| REFERENCE <br> DESIGNATOR | FUNCTION |

## IMPORTANT NOTICE

Texas Instruments and its subsidiaries (TI) reserve the right to make changes to their products or to discontinue any product or service without notice, and advise customers to obtain the latest version of relevant information to verify, before placing orders, that information being relied on is current and complete. All products are sold subject to the terms and conditions of sale supplied at the time of order acknowledgement, including those pertaining to warranty, patent infringement, and limitation of liability.

TI warrants performance of its semiconductor products to the specifications applicable at the time of sale in accordance with Tl's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

CERTAIN APPLICATIONS USING SEMICONDUCTOR PRODUCTS MAY INVOLVE POTENTIAL RISKS OF DEATH, PERSONAL INJURY, OR SEVERE PROPERTY OR ENVIRONMENTAL DAMAGE ("CRITICAL APPLICATIONS"). TI SEMICONDUCTOR PRODUCTS ARE NOT DESIGNED, AUTHORIZED, OR WARRANTED TO BE SUITABLE FOR USE IN LIFE-SUPPORT DEVICES OR SYSTEMS OR OTHER CRITICAL APPLICATIONS. INCLUSION OF TIPRODUCTS IN SUCH APPLICATIONS IS UNDERSTOOD TO BE FULLY AT THE CUSTOMER'S RISK

In order to minimize risks associated with the customer's applications, adequate design and operating safeguards must be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance or customer product design. TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used. Tl's publication of information regarding any third party's products or services does not constitute TI's approval, warranty or endorsement thereof.
