## 5 Volt, Byte Alterable E²PROM

## TYPICAL FEATURES

- High Density 2 Megabit (256K x 8) Module
- Access Time of 150 ns at $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
- Base Memory Component: Xicor X28C513
- Pinout conforms to JEDEC Standard for 2 Megabit E²PROM
- Fast Write Cycle Times
-128 Byte Page Write
—Byte or Page Write Cycle: 5ms Typical
-Complete Memory Rewrite: 10 Seconds
- Early End of Write Detection
- DATA Polling
-Toggle Bit Polling
- Software Data Protection
- Three Temperature Ranges
-Commercial: $0^{\circ} \mathrm{C}$ to $+75^{\circ} \mathrm{C}$
-Industrial: $-40^{\circ}$ to $+85^{\circ} \mathrm{C}$
-Military: $-55^{\circ}$ to $+125^{\circ} \mathrm{C}$
- High Rel Module
-100\% MIL-STD-883 Compliant Components
- Endurance: 100,000 Cycles

## DESCRIPTION

The XM28C020 is a high density 2 Megabit $E^{2} P R O M$ comprised of four X28C513 LCCs mounted on a co-fired multilayered ceramic substrate. Individual components are $100 \%$ tested prior to assembly in module form and then $100 \%$ tested after assembly.

The XM28C020 is configured $256 \mathrm{~K} \times 8$ bit. The module supports a 128 -byte page write operation. This combined with DATA Polling or Toggle Bit Polling, effectively provides a $39 \mu \mathrm{~s} / \mathrm{byte}$ write cycle, enabling the entire array to be rewritten in 10 seconds.

The XM28C020 provides the same high endurance and data retention as the X28C513.

FUNCTIONAL DIAGRAM

PIN CONFIGURATION

## PIN DESCRIPTIONS

## Addresses ( $\mathrm{A}_{0}-\mathrm{A}_{17}$ )

The Address inputs select an 8-bit memory location during a read or write operation.

## Chip Enable ( $\overline{\mathrm{CE}}$ )

The Chip Enable input must be LOW to enable all read/ write operations. When $\overline{\mathrm{CE}}$ is HIGH , power consumption is reduced (see Note 4).

Output Enable ( $\overline{\mathrm{OE}}$ )
The Output Enable input controls the data output buffers and is used to initiate read operations.

Data In/Data Out ( $1 / \mathrm{O}_{0}-\mathrm{l} / \mathrm{O}_{7}$ )
Data is written to or read from the XM28C020 through the I/O pins.
Write Enable ( $\overline{\mathrm{WE}}$ )
The Write Enable input controls the writing of data to the XM28C020.

## PIN NAMES

| Symbol | Description |
| :--- | :--- |
| $\mathrm{A}_{0}-\mathrm{A}_{17}$ | Address Inputs |
| $\mathrm{I} / \mathrm{O}_{0}-\mathrm{I} / \mathrm{O}_{7}$ | Data Input/Output |
| $\overline{\mathrm{WE}}$ | Write Enable |
| $\overline{\mathrm{CE}}$ | Chip Enable |
| $\overline{\mathrm{OE}}$ | Output Enable |
| $\mathrm{V}_{\mathrm{CC}}$ | +5V |
| V SS | Ground |
| NC | No Connect |

## DEVICE OPERATION

## Read

Read operations are initiated by both $\overline{\mathrm{OE}}$ and $\overline{\mathrm{CE}}$ LOW. The read operation is terminated by either $\overline{\mathrm{CE}}$ or $\overline{\mathrm{OE}}$ returning HIGH. This 2 -line control architecture eliminates bus contention in a system environment. The data bus will be in a high impedance state when either $\overline{\mathrm{OE}}$ or $\overline{C E}$ is HIGH.

## Write

Write operations are initiated when both $\overline{\mathrm{CE}}$ and $\overline{\mathrm{WE}}$ are LOW and $\overline{\mathrm{OE}}$ is HIGH. The XM28C020 supports both a $\overline{\mathrm{CE}}$ and $\overline{\mathrm{WE}}$ controlled write cycle. That is, the address is latched by the falling edge of either $\overline{\mathrm{CE}}$ or WE, whichever occurs last. Similarly, the data is latched internally by the rising edge of either $\overline{\mathrm{CE}}$ or $\overline{\mathrm{WE}}$, whichever occurs first. A byte write operation, once initiated, will automatically continue to completion, typically within 5 ms (see Note 4).

## Page Write Operation

The page write feature of the XM28C020 allows the entire memory to be written in 10 seconds. Page write allows two to 128 bytes of data to be consecutively written to the XM28C020 prior to the commencement of the internal programming cycle. The host can fetch data from another device within the system during a page write operation (change the source address), but the page address ( $A_{7}$ through $A_{17}$ ) for each subsequent valid write cycle to the part during this operation must be the same as the initial page address.

The page write mode can be initiated during any write operation. Following the initial byte write cycle, the host can write an additional one to 127 bytes in the same manner as the first byte was written. Each successive byte load cycle, started by the WE HIGH to LOW transition, must begin within $100 \mu$ s of the falling edge of the preceding $\overline{\mathrm{WE}}$. If a subsequent $\overline{\mathrm{WE}} \mathrm{HIGH}$ to LOW transition is not detected within $100 \mu \mathrm{~s}$, the internal automatic programming cycle will commence. There is no page write window limitation. Effectively the page
write window is infinitely wide, so long as the host continues to access the device within the byte load cycle time of $100 \mu \mathrm{~s}$.

## Write Operation Status Bits

The XM28C020 provides the user two write operation status bits. These can be used to optimize a system write cycle time. The status bits are mapped onto the I/O bus as shown in Figure 1.

Figure 1. Status Bit Assignment

3872 FHD F09

## $\overline{\text { DATA }}$ Polling ( $1 / \mathrm{O}_{7}$ )

The XM28C020 features DATA Polling as a method to indicate to the host system that the byte write or page write cycle has completed. DATA Polling allows a simple bit test operation to determine the status of the XM28C020, eliminating additional interrupt inputs or external hardware. During the internal programming cycle, any attempt to read the last byte written will produce the complement of that data on $\mathrm{I} / \mathrm{O}_{7}$ (i.e., write data $=0 x x x$ xxxx, read data $=1 x x x x x x x$ ). Once the programming cycle is complete, $\mathrm{I} / \mathrm{O}_{7}$ will reflect true data. Note: If the XM28C020 is in the protected state and an illegal write operation is attempted, $\overline{\text { DATA }}$ Polling will not operate.

## Toggle Bit ( $1 / \mathrm{O}_{6}$ )

The XM28C020 also provides another method for determining when the internal write cycle is complete. During the internal programming cycle $\mathrm{I} / \mathrm{O}_{6}$ will toggle from " 1 " to " 0 " and " 0 " to " 1 " on subsequent attempts to read the last byte written. When the internal cycle is complete the toggling will cease and the device will be accessible for additional read or write operations.

DATA POLLING I/O7
Figure 2. DATA Polling Bus Sequence

Figure 3. $\overline{\text { DATA }}$ Polling Software Flow

$\overline{\text { DATA }}$ Polling can effectively halve the time for writing to the XM28C020. The timing diagram in Figure 2 illustrates the sequence of events on the bus. The software flow diagram in Figure 3 illustrates one method of implementing the routine.

THE TOGGLE BIT I/O ${ }_{6}$
Figure 4. Toggle Bit Bus Sequence

Figure 5. Toggle Bit Software Flow

The Toggle Bit can eliminate the software housekeeping chore of saving and fetching the last address and data written to a device in order to implement DATA Polling. This can be especially helpful in an array comprised of multiple XM28C020 memories that is frequently updated. The timing diagram in Figure 4 illustrates the sequence of events on the bus. The software flow diagram in Figure 5 illustrates a method for testing the Toggle Bit.

## HARDWARE DATA PROTECTION

The XM28C020 provides three hardware features that protect nonvolatile data from inadvertent writes.

- Noise Protection-A $\overline{W E}$ pulse less than 10 ns will not initiate a write cycle.
- Default $\mathrm{V}_{\mathrm{CC}}$ Sense-All functions are inhibited when $V_{C C}$ is $\leq 3 \mathrm{~V}$.
- Write Inhibit-Holding $\overline{O E}$ LOW will prevent an inadvertent write cycle during power-up and power-down.

## SOFTWARE DATA PROTECTION

The XM28C020 does provide the Software Data Protection (SDP) feature.

The module is shipped from Xicor with the Software Data Protection NOT ENABLED; that is, the module will be in the standard operating mode. In this mode, data should be protected during power-up/-down operations through the use of external circuits. The host system will then have open read and write access of the module once $\mathrm{V}_{\mathrm{CC}}$ is stable.

The module can be automatically protected during power-up/-down without the need for external circuits by employing the SDP feature. The internal SDP circuit is enabled after the first write operation utilizing the SDP command sequence.

When this feature is employed, it will be easiest to incorporate in the system software if the module is viewed as a subsystem composed of four discrete memory devices with an address decoder (see Functional Diagram). In this manner, system memory mapping will extend onto the module. That is, the discrete
memory ICs and decoder should be considered memory board components and SDP can be implemented at the component level as described in the next section.

## SOFTWARE COMMAND SEQUENCE

$A_{16}$ and $A_{17}$ are used by the decoder to select one of the four LCCs. Therefore, only one of the four memory devices can be accessed at one time. In order to protect the entire module, the command sequence must be issued separately to each device.

Enabling the software data protection mode requires the host system to issue a series of three write operations: each write operation must conform to the data and address sequence illustrated in Figures 6 and 7. Because this involves writing to a nonvolatile bit, the device will become protected after $\mathrm{t}_{\mathrm{wc}}$ has elapsed. After this point in time devices will inhibit inadvertent write operations.

Once in the protected mode, authorized writes may be performed by issuing the same command sequence that enables SDP, immediately followed by the address/data combination desired. The command sequence opens the page write window enabling the host to write from one to 128 bytes of data. Once the data has been written, the device will automatically be returned to the protected state.

In order to facilitate testing of the devices the SDP mode can be deactivated. This is accomplished by issuing a series of six write operations: each write operation must conform to the data and address sequence illustrated in Figures 8 and 9 . This is a nonvolatile operation, and the host will have to wait a minimum twc before attempting to write new data.

## XM28C020

## SOFTWARE DATA PROTECTION

Figure 6. Timing Sequence-Byte or Page Write

Figure 7. Write Sequence for Software Data Protection

Regardless of whether the device has previously been protected or not, once the software data protected algorithm is used and data has been written, the device will automatically disable further writes unless another command is issued to cancel it. If no further commands are issued the device will be write protected during power-down and after any subsequent power-up.

## RESETTING SOFTWARE DATA PROTECTION

Figure 8. Reset Software Data Protection Timing Sequence

Figure 9. Software Sequence to Deactivate

Software Data Protection

In the event the user wants to deactivate the software data protection feature for testing or reprogramming in an $E^{2} P R O M$ programmer, the following six step algorithm will reset the internal protection circuit. After twc, the device will be in standard operating mode.

## XM28C020

## SYSTEM CONSIDERATIONS

Because the XM28C020 is frequently used in large memory arrays it is provided with a two line control architecture for both read and write operations. Proper usage can provide the lowest possible power dissipation and eliminate the possibility of contention where multiple I/O pins share the same bus.

To gain the most benefit it is recommended that $\overline{\mathrm{CE}}$ be decoded from the address bus and be used as the primary device selection input. Both OE and WE would then be common among all devices in the array. For a read operation this assures that all deselected devices are in their standby mode and that only the selected device(s) is outputting data on the bus.

Because the XM28C020 has two power modes, standby and active, proper decoupling of the memory array is of
prime concern. Enabling $\overline{\mathrm{CE}}$ will cause transient current spikes. The magnitude of these spikes is dependent on the output capacitive loading of the I/Os. Therefore, the larger the array sharing a common bus, the larger the transient spikes. The voltage peaks associated with the current transients can be suppressed by the proper selection and placement of decoupling capacitors. As a minimum, it is recommended that a $0.1 \mu \mathrm{~F}$ high frequency ceramic capacitor be used between $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{SS}}$ at each device. Depending on the size of the array, the value of the capacitor may have to be larger.

In addition, it is recommended that a $4.7 \mu \mathrm{~F}$ electrolytic bulk capacitor be place between $\mathrm{V}_{\mathrm{CC}}$ and $\mathrm{V}_{\mathrm{SS}}$ for every two modules employed in the array. This bulk capacitor is employed to overcome the voltage droop caused by the inductive effects of the PC board traces.

ABSOLUTE MAXIMUM RATINGS*

## *COMMENT

Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and the functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## WE Controlled Write Cycle

Note: (4) Due to the inclusion of the decoder IC on board the module the $\overline{\mathrm{WE}}$ and $\overline{\mathrm{CE}}$ write controlled timings will vary. When utilizing the $\overline{\mathrm{CE}}$ controlled write operation all the hold timings must be extended by the worst case propagation delay of the decoder. For a $\overline{\text { WE }}$ controlled write operation $\overline{\mathrm{CE}}$ must be a minimum 125 ns to accommodate the additional setup time required.

## LIFE RELATED POLICY

In situations where semiconductor component failure may endanger life, system designers using this product should design the system with appropriate error detection and correction, redundancy and back-up features to prevent such an occurence.

Xicor's products are not authorized for use in critical components in life support devices or systems.

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.
